are the cause. Let us next consider the condition to which the term gastrostaxis has been applied. Many authors have been struck with the frequency with which young women vomit blood—for example, Dr. E. W. Goodall found that out of 36 cases of hæmatemesis under 30 years old 27 were women and 9 were men. Formerly, this was ascribed to vicarious menstruation; when this explanation was discarded these bleedings were considered to be due to gastric ulcer, and accordingly we were taught that gastric ulcer was far commoner in women than in men, and it was especially seen in young women. But suspicion as to the correctness of this view was aroused by the facts that in men gastric ulcer was commoner at a considerably older age, and gastric ulcers found in the post-mortem room were no commoner in women than in men. Then several cases were operated on for hæmatemesis and no ulcer was found, and cases were published in which a careful search after death had failed to demonstrate the presence of any ulcer. When such a case was examined during life the blood was seen by several surgeons to be oozing from many minute points usually grouped together.

That there is a disease far commoner in young women than in older women or men characterised by dyspepsia, pain, vomiting, and hæmatemesis is allowed by most recent authors who have written on the subject. I have published many such cases.[2] Since I did so others have come to my notice. Dr. A. E. Boycott has given me particulars of a woman, aged 35, who had indigestion with severe hæmatemesis in 1905, and in 1906 when it was nearly fatal the stomach was opened, and all that was seen wrong was a large area of congested bleeding mucous membrane. Mr. J. S. Watson tells me of a woman, aged 25, who for many months suffered from pain in the stomach, nausea, vomiting, and hæmatemesis. She was thought to have a gastric ulcer, but on opening the stomach at an operation no trace of an ulcer or cicatrix could be found. Hæmatemesis and melæna have continued since the operation. A woman, aged 44, had been in Guy's Hospital on many occasions for pain, nausea, vomiting, and hæmatemesis; she died outside. The late Mr. W. F. Hearnden sent me the stomach. I could find no trace of any ulcer or cicatrix. A man, aged 36, seen with Mr. A. H. Card. Hæmatemesis and melæna were so severe that we thought he had a duodenal ulcer. At an operation Mr. Arbuthnot Lane examined the stomach and duodenum most carefully, but no sign of an ulcer could be seen. This condition has been called gastrostaxis and the explanation of it that has always appealed to me has been that the disease consisted in a giving way of the walls of minute vessels, that blood first effused under the gastric epithelium broke through this and hence the bleeding. If this view is correct we must suppose the weakening of the blood-vessels to be due to an endothelial toxin and then these cases are allied to the conditions previously mentioned in this paper, in some of which, e.g., purpura hæmorrhagica, hæmatemesis is by no means uncommon; we should then have purpura hæmorrhagica a disease in which an endothelial toxin acted on the vessels in several situations, and gastrostaxis a disease in which an endothelial toxin acted only on the vessels of the stomach and occasionally on those of the intestine, for sometimes the bleeding occurs also in the intestine. Thus Dr. A. G. Gullan[3] reports the case of a girl who had all the symptoms of gastric ulcer, including hæmorrhage; she died suddenly. The stomach showed numerous small hæmorrhagic erosions scattered over its surface, which was congested in certain places; similar erosions were found in the duodenum and jejunum and there were subperitoneal hæmorrhages. Dr. W. P. Herringham also records cases in which the bleeding occurred from the duodenum as well as the stomach, and I have recorded some.[4] As the blood bursts through the gastric epithelium there must be minute erosions, and Dr. C. Bolton, while he agrees that there is a condition most often seen in young women and characterised by dyspepsia, pain, vomiting, and hæmatemesis, inclines to the belief that some or all instances of gastrostaxis are really instances of minute gastric ulcers. The matter is not easy to decide, for the difference between minute ulcers and minute erosions is difficult to make out without the most careful microscopical examination; and the opportunities of this are few, for surgeons have rightly largely given up opening the stomach for gastric hæmorrhage, and the condition we are describing is rarely fatal; but at any rate it must be admitted that an endothelial toxin is quite a likely explanation for these cases, and it would perhaps best explain the cases in which the oozing of blood occurred in other parts of the alimentary tract than the stomach. Further, the possibility that a toxin causes the hæmatemesis is supported by Dr. J. J. Pringle's[5] and other cases of urticaria accompanied by hæmatemesis, for urticaria is often toxic.

Many a time it has happened that a physician or surgeon has, on account of hæmaturia, thought that a stone or new growth existed in the kidney, but a most careful exploration, or in some cases excision, of the kidney has failed to find any satisfactory explanation for the hæmaturia. These are examples of what has been called renal epistaxis, or, to use a phrase more widely employed, essential renal hæmaturia. There are so many causes for hæmaturia that scepticism as to the existence of essential renal hæmaturia is justifiable, but there is no doubt that it exists. I have recently collected several cases.[6] Senator says: "There still remains a group of cases in which nothing can be found in the kidneys to account for the hæmorrhage." Herrick gives the case of a man aged 45, who had had hæmaturia for ten months. The cystoscope showed that the blood came from the right kidney; nephrotomy revealed nothing abnormal. The kidney was healthy histologically. Klemperer describes the case of a young man aged 22, who had hæmaturia which proceeded as shown by the cystoscope from the left kidney. Nephrectomy was done and the kidney was perfectly healthy both to the naked eye and microscopically. Wulff and Schenk describe similar cases, the bleeding coming from only one kidney, which both to the naked eye and histologically was normal. I could quote other cases from medical literature; they will be found in the article on essential hæmaturia to which I have referred. I have carefully read the whole of the literature to which I have access in London, and I think there is no doubt that bleeding may take place from the kidney without there being any evidence to the naked eye or microscope that the organ is diseased. For example, a woman, aged 35, was admitted under Mr. C. J. Symonds for profuse hæmaturia; it appeared that the blood came from the right kidney. This was excised; it was healthy both to the naked eye and histologically. I wrote to the patient 27 months after the operation, and she said that her health and weight had improved greatly; she had had during this time one attack of hæmaturia presumably from the other kidney. This condition occurs both in women and men, but more often in men. The patients are usually under 30; it is very rarely fatal. I submit that the most feasible explanation of these cases is that in them a poison—analagous to the menstrual hormone—is formed somewhere at intervals, and this reaching the kidney by the blood, and having a special affinity for the minute renal vessels so damages them that they rupture and the blood escapes; if this is so these cases have the same explanation as those of bleeding from other parts of the body which we have been considering.

It is well known that hæmatemesis is an early symptom of splenic anæmia and that it occurs long before the final stage of hepatic cirrhosis. May it not be that here we have absorbed from the spleen and carried to the stomach by the blood, a toxin having the property of damaging the gastric vessels and so letting blood through and causing hæmatemesis?

I have left till last the mention of epistaxis, for I have very little experience of it unless as a complication of well-known disease, but there is a very widespread belief that it is especially common in boys at the age of puberty who are perfectly healthy. If this is so, it seems difficult to resist the explanation that the epistaxis is due to the circulation in the blood of an unknown substance which has the special property of damaging the vessels of the nasal septum so as to cause hæmorrhage from them.

I hope you will not consider this address too fanciful, but with the strong evidence we have that the menstrual flow is provoked by a hormone secreted by the ovary, it seems to me worth while to consider whether any pathological hæmorrhages might not be produced in a similar way, and I think it possible that they may, being caused by endothelial toxins which act on the walls of the vessels from which the bleeding comes.

MALIGNANT DISEASE OF THE TESTICLE AND THE TREATMENT OF IT BY RADICAL OPERATION.

BY H. MORRISTON DAVIES, M.C. CANTAB., F.R.C.S. ENG.,
ASSISTANT SURGEON, UNIVERSITY COLLEGE HOSPITAL, LONDON.

TUMOURS of the testicle, owing to their peculiar and complex pathological characteristics, have been much described and frequently and variously classified. Yet our knowledge of the morbid anatomy of malignant disease of this organ increased very slowly until Nicholson in his admirable paper, "New Growths of the Testicle,"[1] described the macroscopic and microscopic appearances of 63 specimens from the Guy's Hospital Museum and gave a lucid and comprehensible grouping of the various tumours.

It may here be said that "tumours" is used as synonymous with malignant disease, since with the rare exception of fibroma and adenoma, the existence of which is not universally recognised, all neoplasms of the testicle are malignant in a greater or less degree. The following classification of tumours is based mainly on the work of Nicholson:—

Embryoma	... ...	Solid. Cystic (dermoids).
Carcinoma	... ...	Encephaloid (Alveolar. / Non-alveolar.) Scirrhus.
Sarcoma	... ...	Round celled (lympho-sarcoma).
Endothelioma	...	Lymph-endothelioma. Hæm-endothelioma.

Apart from the endothelioma each of the three types is claimed by different authors as the commonest form of neoplasm of the testicle.

Embryomata are composite tumours containing elements derived from epiblast, mesoblast, and hypoblast, and are developed in the body of the testicle, probably in the region of the rete testis, and not in the epididymis, although this part of the organ may be included later by the growth. The origin of these tumours is not absolutely determined, but Nicholson says: "There can be no doubt that these tumours which contain derivatives of the three blastodermic layers must have originated in a cell which is analogous to an ovum (including a spermatozoon) or one of its earliest divisions—i.e., a cell which is still capable of producing the three primary layers of the embryo" (p. 308). At first benign, any or all of the component parts may undergo malignant change. When two or more layers are so affected a mixed tumour is the result; when hypoblast alone, the tumour assumes the characters of a columnar-celled carcinoma; when mesoblast alone, of a sarcoma or myxo-sarcoma; when epiblast alone, of a dermoid or of a growth closely resembling a chorion-epithelioma.

Nicholson further emphasises the fact that "not only may one layer be greatly in excess of the others, but one tissue may assume this supremacy" (p. 304). One case which he quotes in illustration "consists almost entirely of striped muscle." He continues: "To distinguish these tumours from dermoids, they are called solid embryomata, whereas dermoids are known as cystic embryomata" (p. 304). Nicholson further points out that "the chief point which distinguishes these 'cystic' from the 'solid' embryomata is the comparatively high degree of development which their structures have obtained" (p. 304).

When two only of the three layers are found in a mixed tumour the missing layer is generally the epiblast, the reason of which may be aborted development or incomplete examination. In a few cases, however, the epiblast is represented not only by areas of stratified epithelium and cell nests, but also by elements of a chorion-epitheliomatous nature. It is now generally held that the presence of syncytium and of Langhans's cells does not imply the inclusion of fœtal membranes, and that they are developed from the epitheliomatous cells of the epiblast.[1,2]

The solid embryomata may in macroscopic section appear as solid tumours, as solid tumours containing cystic spaces, or the whole body of the tumour may be converted into cysts of varying size separated by strands of fibrous tissue. In all cases the tumour is surrounded by the tunica albuginea, usually thickened, and the epididymis is to be found on the posterior aspect unaffected, compressed by the growth or occasionally incorporated into the tumour. These embryomata are classed by Bland-Sutton under the name of cystic disease of the testicle.[3]

The cystic embryomata or dermoids are very rare and differ from the preceding in that they show a highly differentiated structure; they are composed of a thick-walled cyst containing embryonic rudiments, teeth, hair, sebaceous matter, portions of the nervous system, &c. Barrington has described what is probably a unique case of a dermoid cyst associated with a new growth, and suggests that "the tumour has arisen in a teratoma from some hypoblastic structure."[4]

Foulerton[5] regards columnar carcinoma as the commonest form of malignant disease of the testicle, but Nicholson is of opinion that all the cases of columnar carcinoma are in reality teratomata, and recognises only encephaloid carcinoma which he subdivides into the alveolar and non-alveolar forms, and scirrhus carcinoma, which latter is very rare.

Sarcomata develop from the intercanalicular connective tissue, and are regarded by Aschoff[6] as the commonest variety of testicular neoplasm. They are mostly of the round-celled type known as lympho-sarcoma. Ewing states that "the disease is distinguished in the majority of cases by the involvement of both testicles, by its rapid course, by the development of multiple metastases, specially in the skin, and by its histological structure which resembles a lympho-sarcoma."[7] Sarcomata are very liable to degenerate and to increase suddenly in size as the result of hæmorrhages into the degenerated areas.

Endotheliomata do not present characteristics which differ materially from such tumours developing in other organs.

Diagnosis.

A patient with malignant disease of the testicle may present himself with all or most of the symptoms and signs distinctive of a growth of that organ, but it is by no means a rare occurrence that the clinical manifestations are so uncharacteristic that the nature of the disease, or even the seat of the primary lesion, is not recognised. It is therefore necessary to describe: A. The clinical picture characteristic of a growth of the testicle. B. Certain aberrant types in which the difficulties in diagnosis are due to: (1) the nature of the history; (2) the presence of a hydrocele; (3) the degeneration of the growth; (4) the patient seeking advice on account of symptoms produced by the secondary growths.

A. *The Clinical Picture Characteristic of a Growth of the Testicle.*

The patient seeks advice on account of a swelling which he has noticed for some months. Pain is rarely a prominent feature. There is a previous history of venereal disease in the majority of the cases and sometimes of trauma.

Physical Signs of the Tumour.

Position.—Russell Howard[8] found that 15·7 per cent. out of 57 cases of undescended testicle had malignant disease of that organ. The testicle has been more often affected when imperfectly descended than when retained in the abdomen. On the other hand, no case of malignant disease of a testicle misplaced in the perineum has been recorded. In a normally placed testicle the tumour is entirely scrotal, or fills the scrotum and reaches up to the external abdominal ring.

Size, shape, outline, surface.—The size varies from that of a hen's egg to that of a cocoanut. The characteristic shape is oval, but there may be one or more rounded bosses projecting from the surface due to the presence of degeneration in the tumour or of fluid in the tunica vaginalis. The outline is well defined, smooth, and rounded. Posteriorly the epididymis may be felt firmly attached to the growth but not involved by it; with increase in size of the tumour the epididymis becomes increasingly compressed and incorporated in the growth. In the later stages when the growth has spread through the tunica albuginea the surface of the tumour becomes irregular and the outline of this part less well defined. The surface of the growth, even when completely enclosed in the tunica albuginea, is always slightly lobulated.

Consistence.—The tumour, apart from any associated hydrocele, may give the feel of a hard or soft solid, or of an elastic or fluctuating mass. Not infrequently the consistence of the tumour varies in different parts. This is specially the case when the growth is degenerating.

Translucency.—An associated hydrocele will be translucent, but the growth is opaque. This examination is useful when there is difficulty in determining how much of a swelling is due to an overlying collection of fluid in the tunica vaginalis.

Sensibility.—Pain is rarely a predominant feature unless the scrotum is implicated. There is a surprising absence even of tenderness. Testicular sensation may occasionally be obtained from the posterior part of the swelling.

Attachments.—Except when the growth has ulcerated through the tunica albuginea the tumour is freely moveable.

Weight.—Much importance is laid in text-books on the weight of a testicular tumour; "as heavy as a stone," &c. Any dependent swelling feels heavy and a tumour weighs more than an equal bulk of water, but not necessarily more than any other solid enlargement of the testicle, and too much reliance should not be placed on this sign as of diagnostic value.

Cord.—The vas is rarely affected, but an irregular lobulated thickening due to extension of the growth may sometimes be felt occupying the lower part of the cord. The vessels of the cord may be enlarged or increased in number, and this can be recognised clinically by a uniform increase in the size of the cord and occasionally by an exaggeration of the pulse in the artery of the vas on the affected side.

Scrotum.—This shows no abnormal change except in very advanced cases when the growth has become adherent to the skin.

Rectal examination.—No change, the result of the neoplasm, is to be detected by palpation of the lower end of the vas and the vesiculæ seminales.

Glands and secondary deposits.—The lymphatics of the testicle run to the lumbar glands round the aorta and vena cava, and it is therefore the upper part of the abdomen that must be particularly examined for evidences of glandular involvement. In the later stages glands in the posterior triangles of the neck or in the inguinal region may become implicated. The inguinal glands are not affected primarily except when the scrotal tissues are invaded by the growth. In cases of sarcoma the metastases are probably disseminated by the blood stream; deposits may therefore be found in any part of the body.

B. *Aberrant Types.*

1. *The nature of the history.*—An embryoma may not develop malignant characteristics for many years. The length of the history, dating it may be even from early childhood, must not be regarded as a point against malignant disease; indeed, if there has been any increase in the size of the swelling other than that due to hydrocele, or if the tumour has become painful, the length of the history should directly suggest that the testicle is the seat of an embryoma. When there is a history that the increase in size was first noticed after an injury, and specially when the swelling has been subsequently tapped and clear or blood-stained fluid withdrawn, the condition may be mistaken for a hæmatoma.

2. *The presence of a hydrocele.*—Hydrocele complicates growth in the great majority of cases. The hydrocele may exist at one pole of the tumour only. There may be a collection at either pole united by an isthmus, or the tunica vaginalis contains a small quantity of fluid evenly distributed. None of these cases should present any difficulty as the result of the fluid; but when the tumour is comparatively small and the hydrocele sufficiently large to envelop the testicle the increase in size of the latter may be very difficult to detect.

3. *The degeneration of the tumour.*—Degeneration of the growth when slight causes one or more areas of softening in the tumour, but when a large part of the growth has broken down that part acquires the characters of an opaque elastic cyst. It occasionally happens that the whole anterior part of the tumour is thus affected, while the posterior part retains its former irregular outline. The appearance produced then closely resembles that seen in advanced tuberculous disease of the testicle, with the hard, irregular epididymis lying behind, and the body, enlarged by extension of the disease, in front. In such cases the real nature of the condition may not be suspected until the operation. Syphilis produces a lobulated tumour with areas of softening, but the lobulation is in these cases much more pronounced and the softening due to the breaking-down gumma is more precisely confined to one or more lobule. The softened areas of a degenerated growth do not become adherent to the overlying parts; a breaking-down gumma does.

4. *The patient seeking advice on account of symptoms produced by secondary growths.*—In certain cases the symptoms complained of are those due to the enlargement of the lumbar glands which, pressing on the aorta and vena cava, their branches and tributaries, or on the organs which lie in contact with the affected glands, specially the duodenum and stomach, give rise to a train of symptoms quite unsuggestive of any lesion of the testicle. The patient may not call attention to the primary growth for one of two reasons: either the testicle and tumour have been removed some time previously and the possibility of any association between the present and past illness does not occur to the man, or the enlargement of the testicle, being painless and of long standing, does not cause sufficient disturbance to impress the patient with the necessity of directing attention to the condition. In all cases, therefore, where abdominal symptoms are associated with a tumour of an obscure nature the possibility of a neoplasm of the testicle must be kept in mind.

Prognosis.

Malignant growth of the testicle is a most fatal disease. A tumour known to have been present for many years may at any moment assume a malignant character and cause death in a comparatively short space of time. Chevassu[9] has collected the statistics of 100 cases treated by castration; of these, 81 died and 19 were cured. His figures are as follows:—

Died, 81.		*Cured, 19.*	
Within 1 year	38	Alive 4 to 5 years after ...	4
,, 2 years	17	,, 5 ,, 6 ,, ,, ...	4
,, 3 ,, ...	9	,, 6 ,, 7 ,, ,, ...	5
,, 4 ,, ...	2	,, 7 ,, 8 ,, ,, ...	1
Date uncertain	15	,, 8 ,, 9 ,, ,, ...	3
		,, 9 ,, 10 ,, ,, ...	2

Early diagnosis and the removal of the testicle with the lymphatics and surrounding fascia and the glands in the lumbar region offer the only hope of decreasing so appalling a mortality.

Treatment.

Very slowly has it dawned upon surgeons that malignant growths of the testicle should be treated in the same rational manner as malignant disease of the tongue or breast—so slowly, in fact, that since Grégoire[10] did the first complete radical operation in 1905 only 12 cases treated in this manner have been recorded. At the present time every surgeon recognises the imperative necessity of removing the glands and lymphatics (with the surrounding fascia) which drain an area, such as the tongue or breast, the seat of a malignant growth; and the enucleation of the infected glands in such cases is regarded in almost the same light as attempting no gland operation whatever "because there is no clinical evidence of involvement." There is no reason why the same radical treatment should not be adopted in cases of malignant disease of the testicle; that the glands are at a distance from the primary growth and need a much greater amount of care and trouble to remove is no contra-indication whatsoever. It is quite feasible (and the danger of the operation is incomparably small compared with that of recurrence when the testicle only is removed) to take away the testicle, cord, the artery and veins of the vas up to their origin from the aorta and entry into the vena cava or renal vein, the lymphatics draining the testicle, the glands into which they drain, and the surrounding fascia in one piece. The heavy mortality from recurrence in cases of simple castration, the proportionate frequency with which glands that could not be felt clinically and apparently normal macroscopically have been found on microscopic examination to be invaded by growth, should be sufficient to make the radical operation the routine procedure,

Before giving details of the operation a fuller understanding of the lymphatics of the testicle is necessary. Numerous experiments have been made by the injection of coloured fluids and dissections by Jamieson and Dobson,[11] Most,[12] and Cunéo.[13] These researches have shown that the glands which are in direct communication with the testicle lie on either side, over, and between the inferior vena cava and the aorta usually between the level of the bifurcation of the aorta below and the renal veins above, but that occasionally

a gland may be found as low as the bifurcation of the common iliac, and as high as just above the renal veins. From this group of glands lymphatics pass out laterally, upwards and downwards to other glands, the uppermost of which are in close relation to the receptaculum chyli. From clinical evidence (and the ease with which injected substances pass through the primary into the secondary group of glands) it seems that the secondary outlying groups may be infected soon after the primary ones have become diseased. Certain it is that when once the glands have become palpable dissemination of the disease progresses rapidly.

The secondary glands lie so high up in the abdomen and are so covered by the duodenum, pancreas, &c., that they are very difficult of access. So long as the diagnosis of growth of the testicle is made fairly early, and the radical operation is undertaken before the primary group of glands is extensively implicated, it is sufficient if these only are removed. The lymphatics of the primary group connected with the right testicle lie to the outer side and over the vena cava, between it and the aorta, and over the right half of the aorta, while those connected with the left testicle have no relation to the vena cava but lie over and on the left side of the aorta. The glands have been removed by the intraperitoneal and the extraperitoneal routes; the latter is undoubtedly preferable.

The Radical Operation.

The incision which has been most often employed to allow of removal of the testicle and cord and to give access to the lumbar glands commences over the upper part of the scrotum, extends up to the external ring, along the inguinal canal, and is prolonged to a point half an inch above the anterior superior spine; the incision then curves upwards till it reaches the costal margin at the level of the tenth rib. At the beginning only the first part of the incision to the external ring is made and the testicle and cord are dissected free. If there is any doubt as to the diagnosis the testicle should be incised at this stage. If malignant disease is present the operation is continued. The incision is prolonged in the direction defined above and carried through the muscles of the abdominal wall until the peritoneum is reached. The cord is traced till it passes through the internal abdominal ring, and then while the sides of the incision are strongly retracted slight tension is applied to the cord so that its further course may be easily recognised. In its retroperitoneal course the vas is adherent to the posterior aspect of the peritoneum and the next stage in the operation consists in freeing the cord and reflecting the peritoneum mesially. The cord is traced down well into the true pelvis and there divided between two ligatures, the cut surfaces being treated with the cautery or pure carbolic. This may be regarded as the first stage in the operation and requires no extraordinary care. The second stage consists in the free dissection of the fascia over part of the iliacus and psoas muscles together with the contained spermatic vessels and lymphatics and the removal of the glands from off the inferior vena cava and aorta.

When the vas has been divided the spermatic vessels are seen no longer to form a rounded bundle but to become spread out. It is therefore necessary to make a wide dissection of the fascia. On the outer side this should extend to the outer border of the psoas. On the inner side the line of division of the fascia should pass mesially so as to cross the common iliac at its bifurcation; the ureter will here be encountered and must be freely exposed. The dissection is then carried along the inner side of the common iliac vessels up to the bifurcation of the aorta. When the left testicle is affected the inner boundary is carried up along the right border of the aorta, and special care must be taken not to injure the inferior mesenteric artery. When the right testicle is the seat of the tumour the inner border is continued over the middle of the aorta. In both cases the upper limit is the upper border of the renal veins. Between these boundaries all fascia, lymphatics, and glands must be removed. During the dissection the spermatic vessels are traced up to their junction with the main vessels and must be ligatured and divided. When all bleeding points have been secured the peritoneum is allowed to return into position, and the abdominal wound is closed without drainage, each of the muscles being stitched up separately.

Up to the present published results show that the radical operation for the complete removal of the testicle, glands, and lymphatics, with adjacent fascia, in one mass has been done 12 times.*

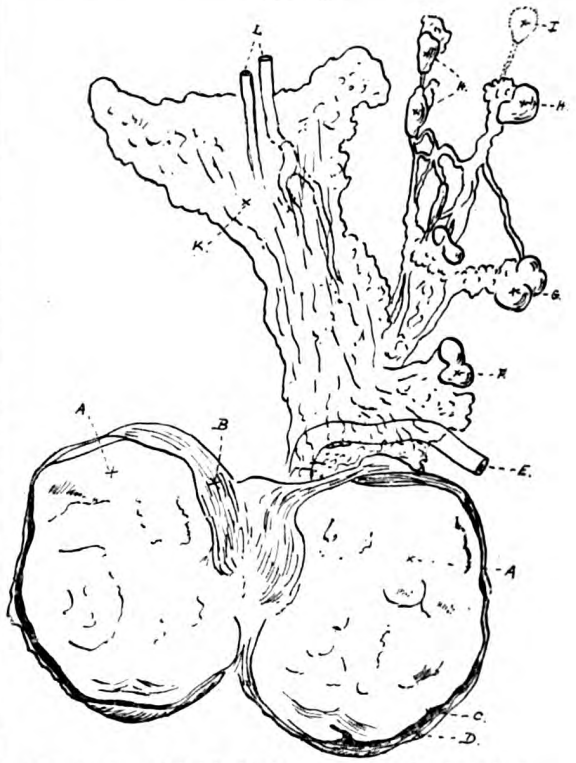
The present case which I have to record is, therefore, the thirteenth in the series.

Notes of Case of Radical Operation.

The patient was a boy, aged 17. The left testicle was fully descended and quite normal. The right testicle had never entered the scrotum, but was situated outside the external abdominal ring. He sought advice because of the swelling of the right testicle which had been noticed for four months. There was no pain, and the chief trouble was the discomfort of the lump in the lower part of the abdomen. There was

FIG. 1.



Reproduction of sketch showing parts removed; the testicle has been cut open longitudinally. A, Body of testicle, almost completely replaced by growth. B, Epididymis. C, Tunica albuginea. D, Tunica vaginalis. E, Vas deferens. F, Gland, level of bifurcation of common iliac. G, Gland, level of bifurcation of aorta. H, Glands, situated over the inferior vena cava and right side of the aorta. I, Gland, level of renal vein and removed separately (Fig. 3 is from sections cut from this gland). K, Fascia over the psoas. L, Spermatic vessels.

a lump in the groin 3 inches long by 2 inches broad, which was evidently a swelling associated with the testicle, as the cord could be felt passing up from the swelling into the inguinal canal, and testicular pain was elicited by pressure on the deep aspect of the mass. The outlines were well defined and smooth and the surface slightly lobulated. The swelling was firm and yet gave a distinct sensation of fluctuation, but the deeper part was hard and inelastic The whole tumour was opaque to transmitted light. It was not

* I am not including in this group Roberts's case (14), in which the glands were removed 14 months after the testicle on account of recurrence of the growth; nor Bland-Sutton's case (15), in which he shelled out an enlarged gland but did not deal with the intervening tissue nor do a complete dissection of the lymphatics.

fixed to the skin or deeper structures. The cord was normal; there was no increase in size nor pulsation. No palpable glands; no evidence of secondary deposits.

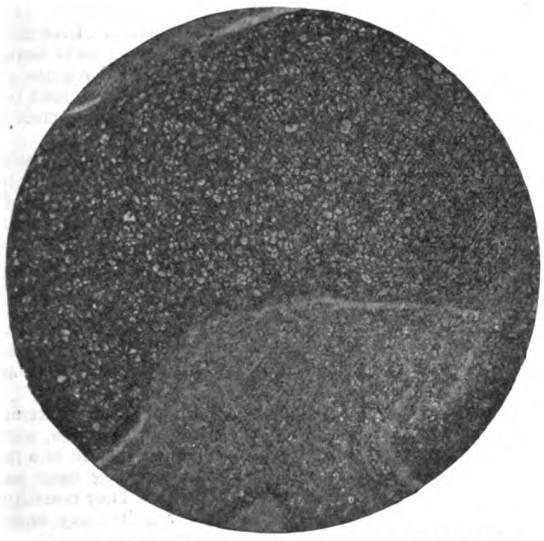
On April 5th, 1911, I did the radical operation as already described. Having made an incision over the swelling and freed the testicle, I incised it to confirm the diagnosis of tumour. The incision was then prolonged up to the costal margin through the muscles of the abdominal wall and the peritoneum reflected. A hernial sac was found running along with the cord, and this was cut off and the base ligatured in the usual way. The vas was traced into the pelvis, ligatured, and divided. The fascia over the psoas, including the lymphatics and glands lying in relation to the vena cava, and the right part of the aorta from just below the bifurcation of the common iliac to just below the renal vein, was dissected up. The testicle and tumour, lymphatics, glands, and fascia were then all removed in one piece. (Fig. 1.) When this had been done another gland previously overlooked was seen lying on the vena cava at the level of the renal vein; this was removed separately. The abdominal wall was stitched up in layers without drainage. Union by first intention. The patient returned home three weeks after the operation.

Examination of Tumour.

The tumour was hardened and then incised. The tunica vaginalis contained practically no fluid. The whole of the body of the testicle is invaded by solid growth; the tunica albuginea is somewhat thickened, but is everywhere intact and encloses the tumour. The epididymis lies slightly compressed on the posterior aspect of the growth. The cord is not invaded but is larger than normal, due to some increase in the vessels. The cut surface is reddish-brown in colour with patches of yellow-grey (commencing degeneration) in the centre.

Microscopically the tumour is a solid embryoma. The mesoblast is represented by cartilage (Fig. 2), and sarco-

FIG. 2.



Micro-photograph of mesoblastic elements (cartilage) in tumour. × 100.

matous and myxomatous tissues; the hypoblast by cysts lined by columnar epithelium. Some of the cysts show considerable infolding of the epithelial lining. No trace of epiblastic elements (except one very doubtful cell nest) can be seen, although sections were taken right across the tumour.

Section of the highest gland, which is 1 cm. in diameter by 0·5 cm. thick, shows well-developed cystic spaces with marked infolding of the basement membrane and is lined by columnar epithelium and goblet cells. (Fig. 3.) A small patch of myxo-sarcomatous tissue is also present.

Summary.

In conclusion, I wish to emphasise the following points:—

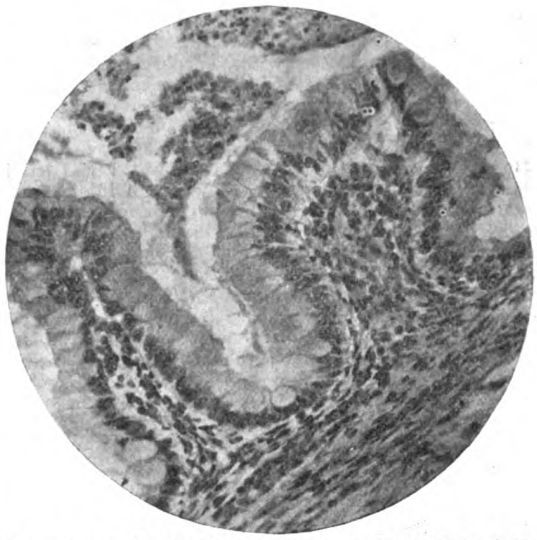
1. All tumours of the testicle must be regarded as malignant.

2. The history of previous venereal disease, the association of the swelling of the testicle with an injury, the length of the history dating perhaps from childhood, must not be allowed to outweigh clinical evidence.

3. Always suspect a tumour of the testicle when there is an oval swelling which is not translucent and comparatively painless.

4. When the tumour is in addition soft or elastic, and the surface shows slight lobulations, regard the suspicions as confirmed.

FIG. 3.



Micro-photograph of portion of cyst in secondary deposit in gland, showing columnar epithelium and goblet cells. × 400.

5. Increased pulsation of the cord is in favour of tumour, but is not pathognomonic.

6. A solid tumour may be so elastic as to give the feel of a fluid swelling.

7. The aberrant clinical manifestations of a testicular neoplasm must be constantly borne in mind.

8. If the diagnosis is uncertain and the possibility of growth is entertained the tumour must be explored. Should the tumour be syphilitic, no harm will have been done; if tubercular or a hæmatoma, operation is the correct treatment.

9. When the diagnosis of tumour is confirmed the complete radical operation, consisting of removal of testicle, cord, lymphatics, and surrounding fascia, and of the lymphatic glands in the region of the aorta and vena cava, must be done, unless the lumbar glands are extensively involved, or there are evidences of metastases elsewhere.

Harley-street, W.

PARTIAL THYROIDECTOMY UNDER LOCAL ANÆSTHESIA, WITH SPECIAL REFERENCE TO EXOPHTHALMIC GOITRE.[1]

BY T. P. DUNHILL, M.D. MELB.

ALL that I shall speak about in this paper is the result of my own experience. The conclusions are such as I have been driven to. I shall not dogmatise if I can help it, because there is much room for legitimate difference of opinion on every aspect of the subject. When I began this work, partial thyroidectomy for exophthalmic goitre was regarded as being at least fairly dangerous, and the operation was not a frequent one. The number of cases which have now been operated upon enables one to speak with more knowledge, but we are still far from finality.

By way of introduction, I might say that I was led into this work in the following way. Through interest in the disease, and reading the medical literature, I had been removing the thyroid glands from milch goats, and feeding the patients on the milk. Thus I had quite a number of patients under me in the out-patient department of the hospital. One day there came a patient who was exceedingly ill, who had no living relations, and who begged for any treatment which would relieve her. After a little time I decided to operate, and placed the whole position before her. She wished for operation. I asked my senior surgeon (Mr. Murray Morton) for a bed. After the operation other patients who had seen her in the out-patient room asked to see her in the ward. Then another asked to be operated upon. Ultimately all were operated upon. Since that time I do not think I have had to persuade a patient to undergo operation. The first-mentioned patient is now doing her work as cook.

I shall not speak of etiology. It seems to me that the chief interest will centre round such questions as, Is surgical interference justifiable? If so, at what stage of the disease is it indicated, and to what extent is interference desirable? Then comes the question of the absolute or relative safety of the patient, and what modifications of technique help to assure this. Finally, and most important of all—in what condition do we leave the patient.

I have written[2] that, judged from the point of view of response to operative treatment, cases fall into four classes:—

I. *The classical type.*—There are present goitre, tachycardia and palpitation, tremor, staring eyes, with or without exophthalmos. There may or may not be complete amenorrhœa, emaciation, alopecia, and other less constant symptoms. But we can detect little or no organic degeneration. The heart has not "broken down," if we may use that term to indicate either definite œdema of dependent parts or irregularity of pulse. It is arguable whether operation should be performed in this class or not. There is the possibility of complete return to health by medical treatment or rest, or with no treatment at all. Also there is the possibility that, in spite of all medical treatment, the disease may progress, to end either in death or in such organic degeneration that return to health is an impossibility. We will discuss that later.

II.—In this class I place those cases in which the disease has progressed until there has been organic degeneration; and among them there have been some complete wrecks—irregular heart, œdema, enlarged liver. The existence of this class at all (and it is a comparatively large one) is some answer to the query as to whether cases in the first class should be operated upon, and it is certainly some answer to the statement still made sometimes that all patients ultimately get well if they live long enough. It has been stated that cases in this class are too far advanced for operation, I think for two reasons: (1) that they are too ill to stand the operation; and (2) because degeneration of organs has advanced to such a stage that improvement is impossible. We will discuss that also later.

III.—In this class I place the cases in which the thyroid gland is quite small, in which it can sometimes scarcely be detected; and yet, associated with that small gland, there may be an extreme degree of one or more of the characteristic signs. There may be absence of tremor or of exophthalmos, though either or both may be excessive. There may be smothering sensations or flushings. In spite of a rapidly beating heart the patient is usually over-fat, if one may use the term.

IV.—In this class I place the cases in which there are some thyrotoxic symptoms, associated with a goitre which is not truly exophthalmic in type. I do not mean by this cases of simple parenchymatous goitre which have been in existence for some years, and have then become exophthalmic in type. Those are among the worst of cases. But there are some cases of adenoma of the thyroid in which the position of the adenoma behind the sternum or clavicle, or the adenoma, apart from any question of position or size, seems to irritate the surrounding gland tissue and cause some tremor, some staring of the eyes, and make the heart more easily excited.

To speak of the considerations which influence one in deciding whether to operate in each class one has to take into account the position in life of the patient and the severity of the case in relation to the progress made under medical treatment. If a patient has means and leisure, and the symptoms are not progressing, and one feels that there is no danger of the heart condition passing from mere irritability into organic change, then medical treatment could safely be persisted with for an indefinite time. Against this one has found that again and again a patient has moved on from one practitioner to another, or has stayed away from her own practitioner, and ultimately comes back, with œdema of the feet. I will instance one or two cases.

I recently operated upon a patient who had seen a practitioner in one of our larger provincial towns two years ago. She took his medicine for three months, then went to a Chinese herbalist. She took the drugs of the Chinese herbalist for one year and nine months; she then saw a medical man who sent her to me. This patient's sister had died in a hospital from goitre years before. I think of another case, where a woman had been going along fairly well and seeing me at moderately long intervals. One morning she came with a heart enlarged, the apex well beyond the nipple-line, and an irregular pulse. Some nights previously she had gone to a dance; that, I presume, had been the culminating cause, though it is more probable that the trouble had been progressive before the dance.

I myself refuse to operate until I know that the patient has had three months' efficient medical treatment, unless there are present other circumstances influencing the case, and one is guided by all the circumstances. One man I kept under medical treatment for nearly 12 months, but he could never work with efficiency, always the thumping heart with the least exertion, and often without. At the end of the time I removed one lobe. Response to operative treatment in this class is very prompt, and the cure is complete if organic heart disease is not present, and if sufficient gland is removed. With local anæsthesia and expert operating the danger is *nil*.

In the second class one gets every stage of wreck—extreme emaciation, œdema, sometimes only in feet and legs, sometimes up the whole body, sometimes in the face if the face be low, as during sleep. Pulse irregular; apex beat anywhere between the nipple-line and the axilla. They constitute a class which most men who operate for goitre say should not be touched for two reasons: (1) because operation is too dangerous, and (2) because organic disease has so far advanced that improvement cannot follow. Out of 380 thyroid operations altogether I have performed 19 on cases in this class, and I say that operation is not too dangerous, and that very great improvement follows. One patient was lying on a bed utterly prostrated. She was œdematous; the stethoscope dented the chest wall; the apex-beat was 1 inch outside the nipple-line. She had incidentally freely moveable kidneys, a retroverted uterus, was almost blind (though not old), and whilst in hospital became deeply jaundiced. Dr. White assisted me to remove one lobe, and, later, half the other. The patient now leads a happy life, does light work, walks, and drives. Of course she cannot do hard work, and her heart can never be sound, but she was completely invalided before.

I have reported before the case of a nun, whose face was asymmetrical with œdema every time she slept. Dr. A.

[1] A paper read before the Surgical Section of the Royal Society of Medicine in joint meeting with the Medical Section and the Section of Anæsthetics on Feb. 13th, 1912. The discussion upon it was adjourned.

[2] Brit. Med. Jour., May 22nd, 1909.

Shields helped me to operate upon her three years ago, and she has since been made Mother Rectress of her convent. She says, with a smile, that she "cannot go up and downstairs *too* many times a day." Her pulse is irregular but quiet; and she does her work fairly comfortably. Two patients whom I had placed in this class on account of œdema, and what was apparently heart failure, completely recovered; and each does all the female labour on a farm. I could multiply instances and details. All of these patients may be written to, or letters from them seen. I do not think that any anæsthetist would care to give a general anæsthetic to cases in this class, but under local anæsthesia one can state that the patients stand the operation well. There is only danger under two conditions: (1) operating under an acute exacerbation of poisoning; (2) operating when bronchitis is present.

About the third class, some authors says that even in the smallest glands associated with thyrotoxic symptoms one can detect the active part and remove it. I cannot, and I think it is unwise to remove portions of a gland which is not obviously enlarged, even though all, or most, of the other characteristic signs are present. One wants to be sure that there is no enlarged portion beneath the sternum or either clavicle. If there it is not always easy to detect. Microscopically such glands show acini densely packed with active cells, and the activity of gland tissue per cubic space is so great that if half or two-thirds of the gland is removed the remaining portion is still so poisonous that it produces symptoms; and it seems that those densely packed cells are likely to atrophy from mutual pressure later. That is only opinion, but the few cases of this class that I have operated upon make me disinclined to remove gland substance.

The fourth class I will not take up time speaking about. The response to operation is immediate and complete.

I think that here I should speak of the mortality. That is one of the most important points to the physician who is deciding the welfare of a patient. I have published enough about the first case I lost, removing too much tissue at once with much crushing when one was inexpert. I lost my second case through operating when bronchitis was present, but the pulse-rate was getting higher each day, and the condition was grave; one took the risk to try to save life. Hypostatic pneumonia followed and the patient died. The third case was moribund when I operated. The patient had been ill for some years and became rapidly worse; then she was sent up to me. Her pulse-rate was between 160 and 180; and she was acutely ill. With Leiter's tubes and calcium lactate the pulse came down to 144 one morning, but rose again to the vicinity of 170 to 180. I knew I could remove the larger lobe rapidly. I thought that, even then, if the larger lobe could be removed without much handling it might not be too late. I discussed it with the husband; he could see that she was dying. I did it. It made no difference at all; the pulse kept the same for the next 24 hours, and she died. That woman had two years during which she could have been operated upon safely and completely cured. The last exacerbation came on whilst she was under medical treatment; then it was too late. I have lost one other case, the circumstances surrounding which I cannot publish. That is four deaths in 380 operations of all classes, and in 230 cases of exophthalmic goitre, and for each death there was an accountable reason.

I think the opinion is becoming almost universal that under certain circumstances operation may be necessary in any case, but there are many who would regard it as being only a last resort. For certain reasons I feel strongly that operation should not be regarded *only* as a last resort. So long as it is regarded as a last resort operation cases will be continually progressing from Class I. to Class II., and the practitioner will have taken away from the patient her chance of complete recovery. Also I would like to say that during the last 18 months five cases have been sent to me in which the patients simply died as soon as they got into hospital. Operation was out of the question; they were dying when they arrived, and all of them had been under constant medical attention. One came 160 miles by train, reached the hospital in the afternoon, and died the same night. One drove 20 miles in a conveyance. 200 miles by train, ambulance to a private hospital, and died. One died at home in the few days intervening between the time when she decided to come into hospital and the day when a bed could be ready. One was admitted into a medical ward until a surgical bed could be ready, had diarrhœa and vomiting all the time, and died before operation. One of the deaths after operation which I mentioned might be added to this number, for the patient was practically moribund when she arrived. This would make a total number of six patients, who were sent absolutely too late for surgical interference. That is one aspect of the *dernier ressort* view!

Then, when speaking of the permanent damage which may occur, I would mention one case in which the eyes were so proptosed that the conjunctival mucous membrane was hanging in œdematous folds. Dr. Edward Ryan said that unless the exophthalmos could be relieved by partial thyroidectomy the patient must lose her eyes. I operated with a pulse so rapid that at times it could not be counted. Her pulse is now in the eighties, but one eye has gone completely; and although the cornea is still transparent in the other, we are not yet sure what will happen. Then there are all the cases which have advanced from Class I. to Class II., those in which the damage is irreparable; I think one cannot ignore evidence like that.

There is also the question as to how much gland tissue should be removed. We know the immense physiological importance of the thyroid gland, and yet here we have it poisoning heart muscle, poisoning nerve tissue, causing exopthalmos and emaciation. We have to remove enough to cure the disease, and we must leave enough for physiological purposes, and all the judgment and experience which one has are called for. In young patients, and those not very bad, the larger lobe should be enough, with any mid-lobe or isthmus. In older people, and those in whom the disease is very bad, the removal of one lobe will practically not do any good at all; one lobe and half the other must be removed. If the gland has been big and active, even then the remaining portion may be too large. One has to remember that more can always be removed, but it cannot be put back again easily. One must remove enough, but one must never be hustled into removing too much in order to make a "complete job" at once. Although I now rarely have to operate more than once, it will occasionally happen that more has to be removed in order to completely cure the patient, and in three cases I have operated three times. They were among my earlier cases, and only one lobe was removed at first; they were also among the earlier cases in which I was recognising that part of the second lobe had to be removed, hence I was very frightened of removing too much. So later I removed a third portion. I am sure it was wiser to go slowly and safely in the way I did; it all had to be, in the way of finding out knowledge.

Anæsthesia.—Now as regards anæsthesia, with the exception of a very few cases in which open ether has been given by Dr. W. T. Harse or Dr. Davies, all my operations have been performed under local anæsthesia. I know that in many instances general anæsthesia may be quite safely given, but in a great many instances it cannot. *All* the causes of death in this operation are not known; chief among them are crushing and handling of gland tissue, slow operating, inexpertness. General anæsthesia alone is not the chief cause of death, but I like operating under local anæsthesia; the patients are safe, the distress is negligible, the recurrent laryngeal nerve may be guarded, post-operative vomiting does not occur, pints of fluid may be given by the mouth. And the moment the operation is over the patient is happy enough to smile, and free from the unpleasant sequelæ of general anæsthesia. General anæsthesia could not be given to cases in Class II., and scarcely in the worst cases of Class I. Almost always the upper pole, or a pear-shaped protuberance from the posterior edge of the middle of the lobe, wraps itself tightly around the trachea, almost behind the trachea. In these cases there is a little "drag," but I submit that that protuberance is more safely shelled out and off the trachea by gentle manipulation under local anæsthesia. In many instances, with nervous patients I have placed the apparatus for general anæsthesia on a shelf in the room, and told the patient that she might have it on demand. I have never had to change, and have long ceased to carry the apparatus. Local anæsthesia means using 7 oz. of 2 per 1000 novocaine, and well infiltrating all the front of the neck.

As regards exophthalmos, the reports that occur in the literature differ very widely. I find that if one lobe and a portion of the other be removed the eye corresponding to the

complete removal recedes much more than the other. If sufficient gland substance has been removed to cure the general condition, the eyes, even if they have been very prominent, almost always recede in a longer or shorter time. One patient whose eyes were very proptosed, and looked quite uncanny, became normal in appearance within a fortnight of operation. Another who had two operations took ten months. I have mentioned the patient whose eyes were so proptosed that one was destroyed, the other receded after operation but not completely, and a few always have a little proptosis remaining.

About the parathyroids, I have not evidence from which to speak. In 380 operations I have never seen evidence of tetany. I certainly strip back the posterior capsule as carefully as I can, but I never do the intracapsular ligation of vessels, as insisted on by some American writers. If they are as readily damaged as the literature would show, I must have damaged them many scores of times. At present I have to suspend judgment.

I think, again (this is only opinion), that if the removal is rapid and gentle, removal of one lobe and a half is possibly less dangerous than removal of one lobe alone, for the following reasons. Removal of one lobe, I believe, causes reflex dilatation of the vessels of the other lobe, with increased activity of the gland. The remaining lobe, being tightly encapsuled by its capsule, must pour the results of its increased activity into the lymph and blood vascular systems, with consequent poisoning. If all of one lobe and half the second be removed *without crushing*, the clean-cut surface of the second lobe allows free escape for the thyroid secretion and lymph, which is led to the exterior by an efficient drainage-tube. This supposition would certainly not hold good with slow operating or rough handling of the gland. The operation must frequently result in failure if only one lobe is removed, the other lobe being at the same time large and vascular. Removal of one lobe may not do a patient any good at all, and it is because so much thyroid tissue is left behind that the operation is so frequently spoken of as not being successful.

The fear that these patients may become myxœdematous has been expressed to me frequently. The operation is being performed extensively the world over now, and many critical eyes are watching results. I think no case of myxœdema following operation would escape observation. On the other hand, I think the greater fear is that, without operation, many cases will pass from Class I. to Class II., or else come too late for surgical interference.

In Osler's "System of Medicine" the statement is made that the disease is one from which "few recover and some die." Against that one can say that one has seen individuals so miserably wretched that life was burdensome, become in one week absolutely calm, lose all tremor, and in a few weeks able to actively enjoy life; others who though not quite so bad are unable to do work except with constant distress, become in a few weeks able to undertake their duties with comfort. They play tennis, they ride, they dance; one man builds coaches; one, who was very ill, has returned to blacksmithing. If, rarely, there is one in whom, through not removing quite enough tissue, the heart beats still too rapidly, one feels that it is better to err on the safe side, and it does not detract from the result in the cases of scores of patients who are leading vigorous lives.

Melbourne.

THE CHILD STUDY SOCIETY, LONDON.—A conference of combined societies, under the auspices of this society, will be held in the University of London on May 9th, 10th, and 11th, under the presidency of Sir James Crichton-Browne. The subject for discussion at the conference will be "The Health of the Child in Relation to its Mental and Physical Development." Papers will be contributed to introduce discussions on Influence of Defects of Hearing and of Vision in Relation to the Mental and Physical Development of the Child, by Dr. J. Kerr Love and Mr. N. Bishop Harman; the Tuberculous Child, by Dr. Jane Walker; Mental Hygiene in Relation to the Development of the Child, by Dr. T. B. Hyslop; Instruction of the Young in Sexual Hygiene, by Dr. G. Eric Pritchard; and a lecture to the conference on Eugenics and Child Study will be delivered by Dr. C. W. Saleeby.

TUBERCULOUS DISEASE OF THE BONES AND JOINTS:

PRESENT POSITION OF TREATMENT IN LONDON.

BY R. C. ELMSLIE, M.S. LOND., F.R.C.S. ENG.,

CHIEF ASSISTANT IN THE ORTHOPÆDIC DEPARTMENT, ST. BARTHOLOMEW'S HOSPITAL; ASSISTANT SURGEON, METROPOLITAN HOSPITAL; ASSISTANT MEDICAL OFFICER (INVALID SCHOOLS), LONDON COUNTY COUNCIL EDUCATION COMMITTEE.

IT may now be accepted that tuberculous disease of the bones and joints is, in England at least, the most important cause of crippling in childhood. Statistics published in the reports of the Medical Officer (Education) to the London County Council during the past few years leave no doubt upon this point, but it may be well to complete these statistics up to date. The following numbers refer to 3275 crippled children examined by me in the London County Council Invalid Schools during the past five years.

Causes of Crippling in 3275 London Children.

Tuberculous disease of—		Congenital—	
Spine	558	Dislocation of the hip	105
Hip	670	Talipes	91
Knee	298	Various deformities...	31
Ankle	70	Total congenital	227
Elbow	10		
Various bones and joints	28	Rickets	158
Total tuberculous disease	1634	Amputations	67
		Old septic bone or joint disease	78
Paralysis—		Spinal curvatures... ...	80
Infantile	636	Various deformities ...	89
Spastic	255		
Progressive...	32	Total	3275
Various...	19		
Total paralysis ...	942		

In Germany in 1906—at the instance of Biesalski—a complete census of the crippled children was taken. 75,183 were found in the whole of Germany, excluding Bavaria, Baden, and Hesse. The principal groups were:—

Principal Causes of Crippling in German Children.

Tuberculous disease of bones and joints	11,303	Severe scoliosis	9,167
Infantile paralysis	11,165	Congenital dislocation of hip	6,479
		Severe rickets	4,724

The importance of tuberculosis is again evident. That its numbers are apparently lower in Germany is partly due to the inclusion in Biesalski's statistics of many comparatively slight defects, which would not be considered sufficiently severe to necessitate the transfer of the child to a special school. But it is also clear that infantile paralysis, severe rickets, and severe adolescent deformities are more common in Germany than in London.

There is much controversy as to the frequency of chronic pulmonary tuberculosis in childhood. There can be none as to the frequency of tuberculosis of the bones and joints. Some figures, given by Sir George Newman in his report for 1910, are of importance in this connexion. It is there shown that in a large collection of statistics, obtained in course of routine school inspection, the total cases of tuberculosis were made up as follows:—

Phthisis (excluding doubtful cases)...	1243
Other forms of tuberculosis	1625

Unfortunately the nature of the lesion in these other forms of tuberculosis is not stated, but it is certain that a large proportion of them must be cases of surgical tuberculosis, including disease of the bones and joints.

These forms of tuberculosis in childhood are not very fatal. The death-rate among the 1634 children in the London schools was only 2 per cent., although many of the children had been watched for as long as five years. This, of course, does not represent the real death-rate from the diseases. The children in these schools have, as a rule, passed through the more acute stages of their disease, and, indeed, for this reason the figures given above do not represent anything like the total number of such children in London, for there are probably nearly as many again in the various hospitals and infirmaries. The total death-rate is probably about 20 per cent., leaving about 80 per cent. who

recover, most of them with some resulting deformity or defect more or less severe.

On commencing the work of inspecting the London County Council Invalid Schools the extent and severity of these resulting deformities came as a shock, and gave an entirely new insight into the efficacy of the present hospital methods of treating such conditions as spinal caries and tuberculosis of the hip and knee. For example, among the first 180 cases of spinal caries examined in the schools, no fewer than 104 were classed as having a severe angular deformity. The first 210 cases of hip-joint disease I classed as follows:—

Cases of Hip-joint Disease.

Disease quiet—	
With good mobile hip	14
With ankylosis and good functional result	22
With some movement, good functional result	20
Moderate functional result	34
Bad functional result (including 25 excisions)	71
Disease active	36
Amputations	6

7 cases were not fully examined.

At that time I also formed a very bad opinion of the final results of such radical operations as excision of the knee for tuberculosis, and this opinion has been only strengthened after further observations. In 1910, collecting the cases of old excision of the knee seen amongst these school children, I found that I had records of 87 children with 89 excised knees, the operations having been done at various hospitals all over London. Stated briefly the results were:—

Results of Excision of Knee.

Recovered, no deformity—		Deformities—*continued.*	
Free movement	1	Genu varum, 20° or less	8
Ankylosis	5	,, ,, 20° to 60°	8
Still active	7	Shortening—	
Deformities—		Under 1 inch	7
Flexion, 20° or less	19	1 inch to 3 inches	40
,, 20° to 40°	14	3 inches to 6 inches	16
,, 40 ,, 90°	11	Over 6 inches	3
Genu valgum	3		

Note.—Many cases come twice into these figures as having both deformity and shortening; in several the shortening was not capable of measurement owing to the deformity.

This does not quite tell the whole story, as of these children 25 had already undergone a second excision, three a third excision, and one an osteotomy for the correction of deformity.

Sufficient has been said to show the great severity of these deformities resulting from tuberculous disease. They are of as great importance to the community as to the individual. Only those who have had to do with the education of these children, and with attempts to find them work suited to their defective physique, can fully appreciate how necessary it is to reduce all deformity to a minimum. Every severely deformed person is liable to be a constant drain upon the community, and it is evident that our present methods of treating tuberculosis are not as efficient as they might be in reducing this drain to a minimum. It is time that we looked into our methods, to see in what respects they fall short of the ideal, and in what manner they may be improved.

The principles of treatment of these conditions are simple, and have for a long time been well understood and taught; but it is to be feared that, owing to various difficulties, they are not carried out with anything like uniformity. Briefly they are:—

1. Early diagnosis.

2. Exact diagnosis, including routine radiography, so that the cases of focal disease in the bone, capable of radical treatment, may not be missed. This applies specially to disease of the knee and other accessible joints.

3. Correction of any deformity that has already arisen. This is, as a rule, completely neglected in spinal caries, in which disease hyper-extension of the spine in the early stages will gradually undo a part at least of the deformity.

4. Rest and fixation, in that position which will be the best if ankylosis supervenes; for example, the spine to be fixed in slight hyper-extension, the hip extended, slightly abducted and with the foot pointed directly forward, the knee fully extended, &c. The spine and hip can only be satisfactorily fixed with the child recumbent; to attempt to carry out rest and fixation by ambulatory treatment is to neglect this principle.

5. The treatment of abscesses by means as conservative as possible, postponing operative treatment and using aspiration in preference to incision.

6. After-treatment by fixation or support as long as is necessary to prevent subsequent contracture. The complete period of treatment is always to be measured in years.

The exact mechanical methods are a matter for the individual surgeon. Thus, if one surgeon prefers the double Thomas frame, another the Berck frame, a third the Whitman frame for the treatment of spinal caries, it is generally because each knows his own instrument best. The results obtained will depend at least as much upon the individual care of the surgeon as upon the method.

It would be tedious to enlarge further upon the details of treatment, but it is instructive to see to what extent they are, or can be, carried out in the various classes of hospitals and other institutions.

In the large general hospitals and in the children's hospitals the evident chief failure is the short period of treatment of these children as in-patients. This is due to causes that are inevitable—press of work, the numbers awaiting admission, and so on. Nevertheless, it is a defect which at once renders these hospitals totally unsuitable for the treatment of most of these cases. As a rule the children are admitted only for short periods—for the opening of an abscess or for the correction of a deformity; and the main part of their treatment, by rest and fixation, has to be carried out upon them as out-patients, a practical impossibility.

The infirmaries are to some extent liable to the same objection, although there is less reason for hurrying the children out of the wards. But they are more liable to the objection—if only owing to understaffing—that the principles of correction of deformity and of proper fixation are liable to be neglected.

The special hospitals—such as the Alexandra Hospital, The Vine at Sevenoaks, Treloar's Hospital at Alton, and the Liverpool Country Children's Hospital at Heswell—are liable to none of these objections. They can carry out to the full all the principles of correct treatment, and it has been evident to me that the results obtained in these hospitals, as seen in the London County Council schools, are many degrees better than those obtained in the general or children's hospitals.

Three other varieties of country homes require to be mentioned. The so-called country surgical homes, of which there are many around London, in theory possess most of the possibilities of good treatment. In fact, they suffer from many defects—they are too small, are often imperfectly equipped (e.g., have no X ray apparatus), and are looked after by honorary medical officers, who have too little time to give up to the home and are apt to accept and continue the treatment which was being carried out at the time of the child's admission or else to drop treatment altogether. Sometimes these honorary officers lack proper knowledge of the mechanical methods which are required, and sometimes have too great a desire to operate.

Convalescent homes are evidently only suitable for cases sufficiently recovered to require no further treatment.

The Metropolitan Asylums Board Homes, such as those at Margate and Carshalton, have all the same advantages as have the special hospitals. It is to country hospitals of this class that we have specially to look for the improvement in the treatment of tuberculous disease of the bones and joints. These country hospitals present only one defect. On discharge the children are often returned home without instructions and without arrangements for after-supervision. It should be easy to arrange these hospitals to work in close touch with the out-patient departments of the hospitals, receiving children from them directly and without delay and returning them to the out-patient departments when discharged from the country hospital.

To summarise, then, the results of observations upon a large number of children suffering from old-standing tuberculous bone and joint disease in London, these create a profound dissatisfaction with our present methods of treatment. This criticism applies chiefly to our methods of organisation and administration, and the obvious line of advance consists in the increase of special hospital accommodation for these children. Whether this increase should be carried out by

the efforts of the charitable public or at the expense of the rates is a matter for the public themselves to decide. It is, however, clear that the results of defective treatment are so serious in that they produce a large number of cripples, that it is not unreasonable to hold this extra provision should be made at the expense of the rates, and that a large increase in the work that the Metropolitan Asylums Board has commenced at Margate and at Carshalton is justified.

The requirements, then, may be briefly stated:—

1. Increase in the accommodation for in-patient treatment of children suffering from tuberculous disease of the bones and joints, preferably in special hospitals situated in the country close to London.
2. The levelling up of these hospitals by having them staffed and supervised by men who will make a special study of the treatment of tuberculous joints, not only from the point of view of saving the child's life, but also from the point of view of preventing deformity.
3. The provision of extensive open-air wards.
4. Provision for treatment for an indefinite period, and for children of all ages, including infants.
5. Arrangements for the education of the children whilst in the hospital.
6. Proper arrangements for after-supervision in an out-patient department and in the home.

Devonshire-place, W.

TUBERCULOSIS OF THE MESENTERIC GLANDS IN CHILDREN:

ITS NATURE AND TREATMENT.*

BY EDRED M. CORNER, M.C. CANTAB., F.R.C.S. ENG.,

SURGEON AND LECTURER TO ST. THOMAS'S HOSPITAL AND TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

TUBERCULOSIS of the mesenteric glands is a condition often found by the surgeon when operating on the abdomen in children. Indeed, I would go so far as to say that tuberculous glands can be found in the mesentery of the small intestine in nearly every case of illness in a child which necessitates abdominal section. The frequency of tuberculosis of the mesenteric glands has been estimated by physicians and pathologists amongst children dying from some form of tuberculosis to vary from 54 to 78 per cent. It has been found, by post-mortem examinations, that in 22 per cent. of these cases the lesions in the mesenteric glands are the only lesions present, but in children with abdominal signs and symptoms they are present in nearly cent. per cent. of the patients.

These figures give very erroneous ideas to the clinician, and particularly to the surgeon. Abdominal sections are not as frequent in children as they are in adults. But during experience of the surgical practices of St. Thomas's Hospital and of the Children's Hospital, Great Ormond-street, it has been my fortune to see a large number of such operations. And the result of this experience is that tuberculous mesenteric glands will be found in practically every child patient submitted to an abdominal operation. Yet, as these children do well and live long, it must be from its frequency that this form of tuberculosis is one very amenable to treatment, and not of the bad prognosis which physicians and pathologists would have us to believe.

The reason for the great frequency of tuberculosis of the mesenteric glands is to be found in a consideration of the processes of digestion, such processes being regarded in their mechanical or physical characters.

The walls of the small intestine are composed of two complete and uniform coats of muscular tissue. The walls of the large intestine have no such uniform coats; the coat of circular muscular fibres is complete, but the longitudinal coat is gathered into three distinct longitudinal bands. As students of science, we have learned that where there is a difference of function there also will be a difference of structure. And the converse is true, where there is a difference of structure there will be a difference of function. The difference in muscular structure cannot be connected with the production of the different chemical juices—that is a function of the mucous membrane, not of the muscular coat. Therefore the difference in structure between the small and the large intestine must be concerned with their contraction—peristalsis. There is little difference in the contractions of the large and small intestines, except in one detail. The contractions of the small intestine, being more even and equable, are adapted for the passing onward of fluid contents; the contractions of the large intestine are less even and regular, being adapted to the passing onward of solid contents.

If the transition of the contents of our intestines from liquid to solid were accomplished gradually, the structure of the small intestine would gradually shade off into that of the large. This is not so. The structure of the small intestine ends abruptly, and that of the large intestine commences at the ileo-cæcal valve. Then it may be assumed that the physical change in the bowel contents from fluid to solid (accomplished largely by the absorption of water and the deposition of mucus) is accomplished whilst the products of digestion pause and wait at that place—namely, the cæcum.

Hence it will be seen that there is a period of pause in the transit of the products of digestion in the cæcum during which these physical changes are accomplished. This pause is made in a warm, slightly alkaline medium. Besides food, a varied host of micro-organisms is ingested which will flourish and multiply during the pause in the cæcum. This has been proved by means of counting the colonies of organisms grown in cultures from various parts of the alimentary tract. In this way it has been proved that micro-organisms are a hundredfold or a thousandfold more numerous in the cæcum than in any other part of the alimentary tract. It may be assumed true for tuberculosis and other infective conditions of the alimentary tract. Hence they are at their maximum infectivity or septicity in the ileo-cæcal region.

To protect the body against this menace a large amount of lymphoid tissue has been formed in the ileo-cæcal region. Hence the function of the appendix. There must be a continuous "ileo-cæcal" strife between organisms and the lymphoid tissue. And so long as the lymphoid tissue prevails the host is in good health. If the micro-organisms get the best of the ileo-cæcal strife the host is in bad health, and may suffer from appendicitis, colitis, or infected glands in the mesentery.

From the above reasoning there can be no mistake in assuming that the great entrance of tuberculosis from the intestine to the body is by the lymphatics of the ileo-cæcal region, and that, therefore, tuberculosis of the mesenteric glands originates from there. Though there is a considerable risk of the generalisation of tuberculosis from the infected mesenteric glands, in this situation the disease is not necessarily fatal. The children suffer from ill-health and abdominal pains referred to the umbilical region. These pains come on at night and sometimes after food. The loss of appetite, anorexia, is often accompanied by some disturbance of the action of the bowels, more often inactivity and constipation than looseness of the bowels.

It is a fact that I have often done abdominal exploration on such children with chronic ill-health, vague abdominal symptoms and discomfort, &c., with or without a tumour on abdominal palpation. And from a very considerable experience of such cases I can say that tuberculous mesenteric glands and a somewhat dilated appendix containing fæcal material, but otherwise not obviously diseased, are always found. The appendix is removed, whereby a great danger is obviated and a great source of discomfort, from contractions on the fæcal matter (appendicular colic), is avoided. A fortnight or three weeks after operation the patient is sent away to a country home. In nine cases out of ten the improvement is rapid and great. Shortly after the operation the appetite returns, and the patient eats and digests with enjoyment articles of diet which had been interdicted before. Hence there can be no doubt, certainly in my mind, that the appendix is the great (and removeable) source of danger and discomfort in these cases, and that no convalescent treatment should be undertaken until that is done.

About the nature of these tuberculous mesenteric glands there is doubt. Are they due to bovine tuberculosis from ingested milk, or are they due to human tuberculosis? At the present moment I am unable to say. Von Pirquet's test for bovine and human tuberculosis is usually negative. And from its varying results I must conclude that some infections

* Portion of a clinical lecture delivered at the Hospital for Sick Children, Great Ormond-street.

of the mesenteric glands are due to human tuberculosis, some to bovine tuberculosis, and some are due to both. Be this as it may, the clinical indications are clear in the cases of children with dietetic troubles, indigestions, abdominal pains and discomfort, and perhaps colitis; remove the appendix and begin sanatorium treatment a fortnight later.

I would therefore urge the very great frequency of tuberculosis of the mesenteric glands in children, and would advise the removal of the appendix in such cases as a preliminary step to further and "physicianly" treatment.

Harley-street, W.

ENTERECTOMY UNDER SPINAL ANÆSTHESIA FOR ACUTE INTESTINAL OBSTRUCTION IN AN INFANT 24 HOURS OLD; SURVIVAL FOR ONE MONTH.

BY GEORGE E. WAUGH, B.S. LOND., F.R.C.S. ENG.,

SURGEON TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET; AND ASSISTANT SURGEON TO THE HAMPSTEAD GENERAL AND NORTH-WEST LONDON HOSPITAL.

THE record of this case is of interest for the following reasons.

1. The rarity of the condition—congenital hernia of the cord—which was responsible for the acute intestinal obstruction. Coley records that in over 75,000 cases of hernia observed at the Hospital for Ruptured or Crippled, New York, only four such cases were found. The same author, quoting Adler, found that of 94 such cases upon whom laparotomy had been performed in other clinics 29 died within a few days after operation.

2. No case of successful resection of intestine with lateral anastomosis for acute obstruction has yet been recorded in a child of this age. Fairbank and Vickers,[1] in recording a successful resection with the use of Murphy's button in a case of their own, aged 7 months, refer to Collinson's case aged 3 months. (Subsequently a case was recorded in one of the journals of a similarly successful operation at the age of 17 days, but I have been unable to verify the reference.) Parry,[2] in recording a case of his own, aged 6 months, mentions that up to 1909 no case of resection of intestine for acute obstruction under the age of 12 years had survived at the Royal Hospital for Sick Children, Glasgow. Until Fairbank's case of 7 months old no child under 2 years of age had survived this procedure at the Hospital for Sick Children, Great Ormond-street.

3. The use of spinal anæsthesia. To undertake a procedure that in children under 2 years of age is so universally fatal that any survival is considered worthy of record would not have occurred to me had not my previous experience of several hundred cases of spinal anæsthesia in children, as modified by Mr. H. Tyrrell Gray, convinced me that failure in this case could only arise from faulty surgery and not from that hitherto uncontrollable factor—shock. This is a point of considerable importance in view of the fact that when Gray began his work four years ago on the modification of the fluid and the method of administration that would ensure its use with safety in children many surgeons had already committed themselves to the opinion that spinal anæsthesia in children was not an advisable procedure. The published records of his cases amply controvert this view, and the credit for the survival of the above case is entirely due to his method of spinal anæsthesia, that enables shock to be warded off with safety, and not to any new surgical procedure.[3]

The history is as follows. The patient was admitted under my care to the Hospital for Sick Children, Great Ormond-street, on June 2nd, 1910, 18 hours after birth. He was a poorly developed, undersized infant, who had been vomiting continuously since birth and had passed neither gas nor solid matter per rectum. His condition was very feeble and the pulse was uncountable. In the situation of the umbilicus was a tumour about as large as his own head, from the apex of which the umbilical cord had been ligated. The wall of the tumour was an opalescent sac with engorged veins in its substance, the base of the sac being continuous with the margins of a small opening in the abdominal wall. The contents of the sac were clearly seen to be many coils of small intestine (see figure). The abdomen was distended and a brief attempt to reduce the contents through the small opening in the abdominal wall was soon abandoned as hopeless. The reason for failure was two-fold, but was only determined after the sac had been opened. A full dose of Gray's stovaine-dextrin fluid was then injected into the spinal theca in the usual manner by Mr. G. M. Huggins, the resident medical superintendent, and in a short time the operation was proceeded with. Complete anæsthesia and muscular paresis were produced to the level of the seventh thoracic segment. On opening the sac it was found to contain from 1 to 2 feet of coils of small intestine, in parts gummed together by exudate, which was probably due to the fact that at birth an exploring needle had been run into the sac, wounding a coil of intestine with consequent slight escape of contents. Opposite to the apex of the superior mesenteric artery a short Meckel's diverticulum fixed the intestine

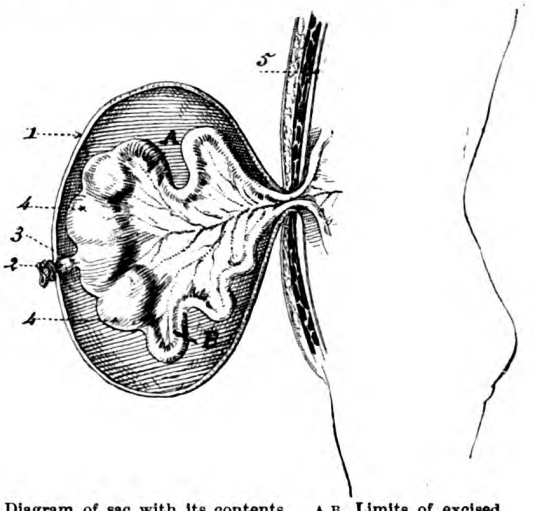

Diagram of sac with its contents. A B, Limits of excised portion of small intestine. 1. Thick-walled opalescent sac. 2. Stump of cord ligated at birth. 3. Meckel's diverticulum. 4. Sacculated portion of small intestine. 5. Parietal peritoneum.

to the interior of the sac at the site from which the cord had been cut after ligation at birth. That portion of the small intestine from which the diverticulum arose was dilated into three saccules resembling in appearance and size large intestine but devoid of appendices epiploicæ. The diverticulum, which was patent at its enteric attachment but blind towards the apex, arose from the free border of the middle saccule. This condition constituted one reason why the reduction of the contents from the sac was impossible. The second reason was due to the fact that the small size of the opening in the abdominal wall would not permit any of the distended coils of the intestine in the sac to be pushed back through it. Even after the intestines had become collapsed their size was so much greater than this opening as to suggest that the whole condition had been brought about by premature closing of the abdominal wall during development and that the intestines excluded in the sac had subsequently continued to grow. The sac was therefore cut away around its base and clamps then applied to the intestine so as to permit of excision of the anchored portion of the gut from which the Meckel's diverticulum arose. This portion included apparently normal small intestine on either side of the three saccules and measured 6 to 7 inches in length. After closing the two ends a lateral anastomosis was performed in the usual way. As the effect of the spinal anæsthesia was now beginning to wear off a second dose was given, and then the opening in the abdominal wall was enlarged so that the entrapped part of the intestine could be inspected and reduction of the extruded portion effected. This was easily achieved, and almost immediately afterwards the child passed a large quantity of meconium per rectum. The edges of the sac

were then trimmed and the laparotomy wound closed by deep and superficial sutures. A noticeable effect of the spinal injection was an immediate improvement of the pulse-rate with a cessation of retching and vomiting.

The recovery was uneventful and the stitches were removed from a perfectly healed wound on the tenth day. The bowels acted normally during that period, and after the first 36 hours there was no vomiting. But the patient was an undersized weakly infant, and at the end of a fortnight was sent home with the hope that his mother's milk, which had been maintained for him, would enable him to thrive. Unfortunately this was not the case, and he died a fortnight later, the cause of death being certified as marasmus. A post-mortem examination was not obtained.

Welbeck-street, W.

A CASE OF SEVERE VERTIGO:

DESTRUCTION OF THE LABYRINTH; CURE.

BY MACLEOD YEARSLEY, F.R.C.S. ENG.,

SENIOR SURGEON TO THE ROYAL EAR HOSPITAL; CONSULTING AURAL SURGEON TO THE ROYAL SCHOOL FOR THE DEAF AND DUMB, MARGATE; MEDICAL INSPECTOR OF LONDON COUNTY COUNCIL DEAF SCHOOLS, ETC.

THE patient, aged 31 years, was sent to me on Dec. 9th, 1909, by Mr. C. A. James, of Stamford-hill, and Mr. E. Jones, of Goswell-road. For 11 years she had suffered from attacks of vertigo. Their onset was sudden, with a feeling of falling, in which direction she could not say, nor could she determine the direction of the horizontal movement which was apparent in surrounding objects. They were followed, about ten minutes later, by vomiting, often prolonged. Her last attack had been on Dec. 7th, when she had awakened suddenly at 3 A.M., with a sensation of giddiness, got out of bed, fell, vomited, and was incapacitated by vertigo and sickness until 8 P.M. Occasionally slight hissing or buzzing tinnitus occurred and was worse during the vertigo, but these noises were by no means always present. The frequency of the vertigo attacks varied; she had passed three years and nine months without one of any severity, but they had of late become more frequent and more severe, and, during the summer of 1909, she had four bad attacks in ten days.

The patient was a hard worker, abstemious, and, apart from her vertigo, in good health. She began, however, to be in constant dread of the attacks, fearing lest she should fall into the fire or sustain other serious injury during their occurrence. Her appetite was not good, but she had no dyspeptic symptoms and never vomited save during an attack of giddiness. A general examination revealed no physical signs.

The patient was deaf on the right side, and she stated that she had discharge from that ear for 18 months after an attack of diphtheria at 18 years of age. On examination the lower half of the inferior segment of the right tympanic membrane was thickened and opaque. The remainder of the membrane was thin and flaccid, especially in the superior posterior quadrant, which appeared to be adherent to the head of the stapes. The left membrane showed inferior thickening. There was nothing noteworthy to be seen in the nose and throat.

Caloric tests were postponed, as the patient was some way from home and did not wish to risk the possible induction of an attack of vertigo. She showed slight horizontal nystagmus on lateral deviation to either side, equal, and probably physiological. Romberg's test showed a tendency to sway towards the right.

Functional tests gave the following results:—Weber: lateralised to the left. Acoumeter: voice and whisper; R., 15 feet; L, *nil*; Rinne: R., double negative; L, positive. Bone conduction: R. greater than -20 sec.; L, -5 sec. Galton-Edelmann whistle: R., 18 580·96 D.V.; L., 40,000 D.V. In the lower part of the scale she could hear no fork on the right side until C 256 was reached, for which she had perception only.

The patient was placed upon general treatment, with large doses of bromide, but this (and later quinine, asafœtida, &c.) had no effect. Seen again on March 30th, 1910, she had had several bad attacks, with severe vomiting. She had noticed that she tended to fall towards the right, and complained that the vertigo left her much more weak than formerly. The caloric test was performed by the house surgeon (Dr. H. More), who found that marked and rather coarse nystagmus to the right occurred after 30 seconds. The question of operation was placed before the patient, who readily consented.

Operation.—On May 28th, 1910, the patient was anæsthetised by Mr. J. Ward Lawson, and the right auricle was turned down by means of Lake's incision. A wide radical mastoid operation was performed; the spine of Henle was well marked, the mastoid being of the infantile type. The antrum was reached quickly, and was found to be of about the size of a split pea. The bridge was removed, leaving the tympanic membrane intact, which, after the extraction of the incus through the antrum, was removed by cutting round with a Sexton's knife. The stapes, with the tendon of the stapedius, having been taken away, the wound was enlarged by the smoothing down of the buttress and all overhanging projections, and a good view of the operation field was thus obtained. One or two facial twitches were noted when working near the pelvis ovalis, and it was found that the seventh nerve was partially exposed in that region. The ampulla of the external semicircular canal having been opened with a fine chisel, that passage was followed into the vestibule, which was thoroughly curetted and swabbed out with a solution of formalin. The tympanic ostium of the Eustachian tube was curetted, the wound was packed, and the auricle was readjusted.

The first dressing was made on May 31st, and nearly all the stitches were removed. No pain or headache was complained of after the operation, and the temperature did not rise throughout the convalescence. There was, however, considerable vertigo, but getting markedly less. The patient left the hospital on June 8th. She still had slight vertigo, but no nausea.

On June 15th she mentioned that she experienced slight staggering when walking, and there was marked nystagmus on deviation to the right. On June 29th she stated that she could walk better and had no vertigo, but on July 6th she said there was always a slight dizziness after walking. The ear healed without complication in about six weeks. The last occasion that she was seen was on Oct. 5th, 1910. She could then walk quite straight; there was no nystagmus, and the feeling of giddiness after walking had almost disappeared.

The patient subsequently obtained a post some distance away, and in a letter dated May 3rd, 1911, she wrote:—

> I am pleased to say that my health generally is much improved and that I have had no attack of sickness until about a fortnight ago, when, after retiring to bed quite well, I was woke up by being sick, but felt no giddiness whatever. I, however, have a tendency to fall, or rather lean to the right side, after having walked for about half an hour; it seems I cannot walk straight, going from left to right unless guided by someone. Otherwise I must say that I am feeling very much better than I was a year ago.

She is now married, and her last letter, dated Jan. 19th, 1912, was in reply to one sent for the purposes of this article. She has replied thus to the following questions:—

1. *Q.* Do you have attacks of giddiness such as you used to experience?—*A.* On an average once in two days I seem to get a giddiness pass through the whole of my body, lasting not more than five minutes.
2. *Q.* Have you any noises in the ear operated upon?—*A.* Occasionally a sound, as of gas; no particular time have I noticed this.
3. *Q.* What is the state of your health generally.—*A.* *Excellent.*
4. *Q.* Have you any attacks of vomiting?—*A.* None, and never felt the slightest whatever.
5. *Q.* Have you still a tendency to lean towards the right side after walking?—*A.* Yes, but it is getting less.
6. *Q.* Have you any difficulty in walking straight?—*A.* I'm afraid this is the greatest of all questions to answer. I certainly cannot walk straight for more than ten minutes when walking quite alone.
7. *Q.* Have you any difficulty in walking or finding your way in the dark?—*A.* Yes; I seem to get a very unpleasant sensation when in the dark; seem to lose control of myself; afraid to venture further on; *cannot imagine a clear space before me*, although I may be certain in myself that the way is clear.

I think, from these replies, that the case may be regarded as a success. The patient is able to live in comfort and no longer has a sudden attack of vertigo, with nausea and vomiting, hanging over her, with the possibility of it lasting for hours. Her replies to the questions are interesting, especially to No. 7, in which I have italicised one sentence.

In the first case of this operation reported by me[1] the patient has since complained of his complete loss of the sense of space when in the dark. A recent experiment, conducted with Dr. F. L. Golla, shows that when rotated even a quarter of a circle with the eyes closed this earlier patient loses all

[1] THE LANCET, Sept. 19th, 1908, p. 871; June 19th, 1909; Feb. 4th, 1911, p. 330.

sense of locality. In this case both ears have been destroyed—the one by operation, the other by disease—and the patient is stone-deaf. I was, therefore, inclined to attribute the effect of darkness to his inability to hear, as much as to the loss of the sense of space. In the later case, however, hearing on one side, as also the vestibule, is normal, yet she has also this sense of insecurity in the dark, although to a less degree.

The investigation of congenitally deaf children, with a view to discover their sensations when in the dark, gave negative results. They appeared to have no difficulty in finding their way and to experience no sense of insecurity, even although rotation with closed eyes (in a series of experiments conducted with Dr. Golla) failed to make them giddy or to disturb their sense of localisation in space. Most of these children had no idea of what giddiness meant.

I have surmised, therefore, that in the case of congenitally deaf children the absence of function in the vestibular apparatus has been compensated by a better development of the muscular sense; and that, in the two adult cases here referred to, that sense has not yet had time to adapt itself to the altered circumstances.

So far as I know, no record has yet been made as to the sensations experienced when in the dark by those who have been deprived of their vestibular apparatus by operation or disease. Perhaps others who have operated upon the labyrinth may be able to throw further light upon the subject.

Queen Anne-street, W.

REMOVEABLE BLADDER SUTURES.

BY COLIN CLARKE, M.B., B.S. LOND., F.R.C.S. ENG.,
LIEUTENANT, R.A.M.C.

THE following method of closing the bladder, with removeable tube sutures, after suprapubic cystotomy, worked so satisfactorily in a recent case that I have ventured to describe briefly the operation.

A private in the 2nd Devonshire Regiment was admitted into the Military Hospital, Cottourra, Malta, in July, 1911, suffering from stone in the bladder. Owing to the cystitis present it was decided to remove the stone by suprapubic cystotomy. Under general anæsthesia the bladder was opened above the pubes and a large, nodular, oxalate stone was removed. The bladder was well washed out with boric acid lotion and a No. 8 rubber catheter was secured in the urethra. The incision in the bladder wall, about 2½ inches long, was closed by means of seven tube sutures.

The tube sutures consist of the following parts:—(1) Strands of ordinary strong silkworm gut; (2) short pieces of glass-tubing, 2 inches long and ¼ inch in diameter; and (3) small brass or steel rings, ½ to 1 inch across. The

FIG. 1.

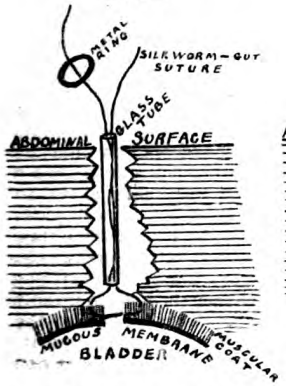

FIG. 2.

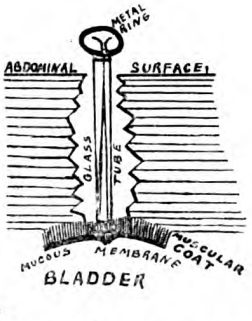

sutures of silkworm gut are passed with a curved needle through the muscular coat of the bladder on both sides of the opening. Each suture is inserted not less than ¼ inch from the edge of the incision and emerges on the cut surface, just short of the mucous membrane of the bladder, as in Fig. 1. The two free ends of the suture are threaded through a glass tube and drawn tight; they are then secured in this position by being firmly tied over the rim of one of the metal rings, as in Fig. 2. The loop of silkworm gut which projects from the end of the tube and passes through the bladder wall acts like the loop of a wire polypus snare and holds the two sides of the bladder incision firmly in contact with each other. The other end of the silkworm-gut suture, knotted over the edge of a ring, as in Fig. 2, is on a level with the surface of the abdomen and is easily accessible for the removal of the suture. To remove a suture the silkworm gut is divided close to the knot, and the knotted end is then pulled on until the suture is withdrawn. One hand at the same time holds the glass tube steady in the wound. The silkworm gut remains quite taut after ligature in the tubes, and does not adhere to the bladder wall on removal.

In the case mentioned above seven sutures were inserted to close the bladder opening and five glass tubes were used to hold them. The two lowest tubes carried two sutures in each. The catheter tied in the urethra was connected with a piece of rubber tubing, which passed into a bowl of antiseptic lotion under the bed. The abdominal incision was partly closed, just sufficient opening being left for the passage of the five glass tubes to the surface.

The suprapubic wound was dressed on the day following the operation, and then on every other day until the eighth day after the operation. For the whole of this time the wound remained clean and free from urine. A slight serous discharge from the granulating wound coagulated and glued the dressings to the tubes and rings. The patient was perfectly comfortable, and the whole of the urine drained away through the catheter in the urethra.

On the eighth day after the operation the tube sutures were removed and the catheter was withdrawn from the bladder. Within a few hours following the removal of the tube sutures urine began to escape from the suprapubic wound, this being the first time for urine to appear since the operation, and a small urinary fistula formed. A catheter was again secured in the bladder and a firm pad of dressings applied to the suprapubic wound. Urine continued to escape from the incision for the whole of the eighth day, but on the ninth and tenth days it greatly diminished, and on the twelfth day it entirely ceased. After this the wound rapidly healed.

I regret now that the tube sutures were not left in position for another four or five days. Eight days form apparently too short a time in which to obtain firm healing of the bladder incision. As long as the tube sutures were left in position the bladder wound remained water-tight and no urine escaped. The urinary fistula which formed after the removal of the tube sutures was only a small one and closed in four days, the suprapubic wound at this period being in an advanced state of healing by granulation.

The tube sutures appear to have some advantages in closing the bladder after suprapubic cystotomy.

1. The tube sutures are easy to insert and to remove.
2. No buried sutures are left in the bladder wall to form a focus for suppuration.
3. The bladder can with safety be sewn up after cystotomy and the patient saved the discomfort of suprapubic drainage.
4. In septic conditions of the bladder the glass suture tubes provide a ready channel of escape for any inflammatory exudates which may collect along the bladder incision.
5. In cases where the bladder has to be reopened after operation, as, for example, to arrest hæmorrhage, remove clots, or provide drainage, the suture tubes afford a ready guide to the bladder incision.

Malta.

ASSOCIATION DES MÉDECINS DE LANGUE FRANÇAISE.—The Thirteenth Congress of French-speaking Physicians will be held at Paris from Oct. 13th to 16th inclusive. The subjects appointed for communications and discussion are: 1. Oxalæmia and Oxaluria. M. Loeper, of Paris, will open the subject with a general exposition, and M. Lambling, of Lille, will give a Chemical Study of Oxalæmia and Oxaluria. 2. Acute Infectious Colitis. M. Cade, of Lyons, will speak of Acute Infectious Colitis in the Adult, and MM. Hutinel and Nobécourt, of Paris, of Acute Infectious Colitis of Infants. 3. The Therapeutics of Hæmorrhagic Syndromes. M. Carnot, of Paris, will open with a general exposition of the subject. M. Sabrazès, of Bordeaux, will discuss the Examination of the Blood in the Diagnosis of Hæmorrhagic Syndromes, and M. Nolf, of Liège, the Physio-pathology of Coagulation of the Blood. Other proposed subjects are: (1) Anaphylaxis Clinically Considered; and (2) Anti-typhoid Vaccination. The secretary-general is Professor Bard, 44, Boulevard des Tranchées, Geneva.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

ABDOMINAL SECTION TWICE ON THE SAME PATIENT FOR ACUTE INTESTINAL OBSTRUCTION DUE TO VOLVULUS.

BY GEORGE HEATON, M.B. OXON., F.R.C S. ENG.,
HONORARY SURGEON TO THE GENERAL HOSPITAL, BIRMINGHAM.

THE following case is of some clinical interest, as the patient has had two attacks of acute intestinal obstruction, due to a volvulus of the sigmoid colon, with an interval of two and half a years between them. The clinical notes of the case are as follows.

First attack.—The patient, a girl aged 16 years, was seen in consultation with her medical attendant on Dec. 16th, 1908. She had then been acutely ill for three days with abdominal pain, vomiting, and complete intestinal obstruction. She was, congenitally, somewhat hydrocephalic, and had since birth suffered from choreic movements of the left side of the body and left limbs. The rhythmical choreic movements involved all the muscles of the left side of the abdomen. She had always suffered from constipation.

Three days previously the constipation had become absolute and the abdomen had rapidly become distended. The pain was at first moderate and colicky in character, but became much worse as distension set in. For the previous two days she had vomited occasionally, and latterly the vomited matter had become stercoraceous in character.

When seen the patient had a marked abdominal facies. The abdomen was extremely distended, tender, and tympanitic all over. There was no sign of any external hernia, and a rectal examination revealed nothing abnormal. The temperature was slightly raised and the pulse-rate varied between 90 and 100. The muscles of the left side of the abdomen were in a state of almost continuous clonic contractions, which ceased abruptly at the middle line.

A diagnosis of acute intestinal obstruction was made, and a laparotomy was performed the same evening in a nursing home. A median incision below the umbilicus was made. On opening the abdomen a loop of large intestine, black and enormously distended, presented itself and seemed to fill the entire cavity. It was brought outside the abdominal cavity and opened, several pints of liquid offensive fæces escaping. The opening was then closed and the bowel was examined; it was found to be an enormously distended sigmoid colon, twisted on its own mesentery from right to left. The bowel was untwisted without difficulty and returned into the abdominal cavity, which was then closed.

Convalescence was uneventful, except that constipation was always a troublesome symptom, and despite the almost constant movements of the muscles of the left side of the abdomen the wound healed by first intention. Her health, except for this constipation, remained good for two and a half years.

Second attack.—On July 22nd, 1911, the patient ate a number of gooseberries, and was seized with acute abdominal pain, with diarrhœa and sickness. This was at first attributed to her error in diet; but the vomiting continued, constipation with rapid abdominal distension set in, and she became daily worse. On July 28th I again saw her. The abdominal distension was then very great, and her symptoms and condition were practically the same as in her previous illness.

Abdominal section was again performed. There were no intra-abdominal adhesions. The sigmoid colon was again found twisted from right to left, enormously distended, and quite black in colour. It was opened and its contents were evacuated. The volvulus was untwisted, and the abdomen was then closed. The bowels were opened naturally soon after the operation. She had a good deal of bronchitis and a very troublesome cough; and the wound, which had been slightly infected during the operation, developed some stitch suppuration, necessitating a somewhat early removal of the stitches.

On August 3rd, after a violent attack of coughing, the scar gave way, and a large number of coils of small intestine and some large intestine were prolapsed into the dressings. She was again anæsthetised, and after carefully cleansing the prolapsed coils and removing the wool which clung tenaciously to them, they were with a great deal of difficulty returned, and the abdominal wound re-sutured. There was no further trouble. She made a slow but uninterrupted convalescence, and has remained in good health since.

Remarks.—The case has several interesting clinical features. Volvulus is very uncommon in young subjects, and it is the only case of the kind I have seen in so young a patient. The recurrence of the volvulus, after an interval of two and a half years, illustrates the well-recognised tendency there is for this form of obstruction to recur. The clonic movements of the abdominal muscles on the left side made me fear for the union of the abdominal wound, and probably in some degree contributed to the reopening of the wound after the second operation.

The question of excision of the distended and twisted bowel—to prevent a recurrence of the volvulus—was raised during the second operation. The patient's condition, however, precluded its performance at the time, and I am afraid the parents would not give their sanction to any such operation now the patient is well.

Birmingham.

A CASE OF POST-OPERATIVE PNEUMOTHORAX TREATED UNDER NEGATIVE PRESSURE.

BY ROBERT NAIRN, F.R.C.S. ENG.

THE following notes of a rather uncommon condition may be interesting.

The patient was a healthy-looking boy aged 8 years. His family history was good. Previous history: He was quite well till the middle of June, 1910, when he was feverish for a few days and later developed whooping-cough. There was no history of pain in the chest. He was first seen by me on August 31st. He was then convalescent from whooping-cough. For two days he had had a temperature of about 103° F. and frequent distressing cough. On examination there was localised fluid at the left infrascapular region adjacent to the middle line. The diagnosis lay between localised pleuritic effusion and hydatid of the lung, with in either case probably commencing suppuration. As the patient had never had any pain, nor even discomfort, hydatid seemed to be the most likely explanation.

On Sept. 2nd, assisted by Dr. W. W. Moore, a portion of rib was excised, but a small opening in the pleura proved that the lung was not adherent. As it was uncertain whether the underlying pleura was diaphragmatic or visceral, the wound was packed with gauze and left for four days. During these four days the patient developed a constant hacking cough, rapid pulse, and very short breathing. On Sept. 6th, on removing the plugs, it was found that the lung had collapsed without forming any adhesions whatever, and the pleura had a whitish unhealthy appearance. On introducing the finger a collection of fluid was discovered after some exploration in the neighbourhood of the spinal reflection of the pleura. Over half a pint of slightly cloudy fluid escaped, apparently an encysted serous collection. We were now faced with a collapsed lung and a probable general infection of pleura.

To keep the lung expanded and to encourage adhesions the wound of the chest wall was closed with sutures as closely as possible and the air removed from the pleural cavity with an aspirator. The breathing and cough were relieved for a few hours and then the trouble gradually returned. Aspiration was repeated several times on successive days, but it was evident that healing would be delayed, as there was no sign of healthy reaction about the wound.

On Sept. 9th the sutures were removed, the pleural cavity was washed out with hydrogen peroxide, and then first a breast-pump and afterwards a Bier's cup was put over the wound and retained in place with strapping and the air partly exhausted. At first the lung expanded fairly well, but the œdema of the wound surfaces soon prevented the cup from maintaining negative pressure in the pleural space. A No. 12 Jaques catheter was then introduced about 4 inches, and cut off about an inch outside the skin level, to preserve communication between the cup and the pleural space. After this there was no further difficulty; the pleura and wound

rapidly grew clean with daily peroxide douching and the cup was left off by Oct. 7th as the wound of the pleura was closed. On Dec. 15th, on examining the chest the lung was found to have fully expanded, with no friction or other unhealthy sound. The patient was in robust health and gaining weight.

The satisfactory result is no doubt to be attributed to the fact that the lung was never permitted to remain collapsed for any length of time, and thus its elasticity was preserved. The defective healing powers of the wound were due to the recent whooping-cough. The method opens up a possibility of further use of such a simple apparatus in operations involving the pleural cavity, especially as the œdema of the outer parts of the wound impaired their vitality enormously.

Hastings, N.Z.

NOTE ON A CASE OF COLD ABSCESS OF THE ABDOMINAL WALL.

BY G. MACDONALD, M.B., CH.B. EDIN.,
HOUSE SURGEON, SCARBOROUGH HOSPITAL AND DISPENSARY.

IN a recent clinical lecture at the Trousseau Hospital M. Savariaud commented on the rarity of cold abscess of the abdominal wall.[1]

On Jan. 1st last a female, aged 19, was admitted to Scarborough Hospital suffering from this complaint. This same patient had been admitted to the hospital on Jan. 18th, 1911. The diagnosis then made was tuberculous peritonitis. Laparotomy was performed, the abdomen being opened in the middle line. A considerable quantity of serous fluid was evacuated and the peritoneum was found to be very considerably thickened. The intestines were adherent to one another and were covered with lymph. The Fallopian tubes, sausage-shaped, bent and covered with adhesions, were removed. The abdominal cavity was drained and the patient made a good recovery. After being discharged from hospital she continued to attend regularly every three weeks as an out-patient.

Three months ago the patient complained of pain on the right side of the abdomen. On examination a small swelling of about the size of a pigeon's egg could be made out in the right hypochondriac region just below the ribs. As the swelling gradually enlarged the pain subsided. The swelling eventually reached about the size of a hen's egg. It had a solid consistence. It did not move with respiration but hardened and disappeared almost completely during contraction of the abdominal muscles. A diagnosis of cold abscess of the abdominal wall was made and the patient was admitted to hospital. She showed no signs of any constitutional disturbance. On admission the temperature was 98° F. and the pulse was 84.

On Jan. 4th an operation was performed. An incision was made over the swelling. A cyst was found embedded in the abdominal muscles, and on opening it about an ounce of pus was evacuated. Iodoform emulsion was introduced and the wound was stitched up, some gauze drainage being inserted at one end of the wound for the first 48 hours. The patient has made an uninterrupted recovery.

The case is interesting from the fact that, according to M. Savariaud, cold abscess of the abdominal wall is usually a primary manifestation of tuberculosis, whilst in this instance it was obviously secondary to the tuberculous peritonitis, infection most probably having reached the abdominal wall by way of the subperitoneal lymphatics.

I am indebted to Dr. J. H. Thornley, honorary surgeon to the hospital, for leave to publish notes of this case.

Scarborough.

[1] THE LANCET, Jan. 6th, 1912, p. 42.

DONATIONS AND BEQUESTS.—Under the will of the late Mr. Francis Tagart, of Old Sneed Park, near Bristol, the University of Bristol and the Bristol Royal Infirmary each receive £1000. Mr. Tagart was for many years connected officially with the Royal Infirmary as a member of the committee.—The Chelsea Hospital for Women has received a donation of £200 from Mr. R. Nivison and a £10 note (placed in letter box) from an anonymous donor.

CLINICAL SECTION.

Exhibition of Cases—Congenital Absence of the Left Half of the Diaphragm Simulating Pneumothorax.

A MEETING of this section was held on Feb. 9th, Sir WILLIAM OSLER, the President, being in the chair.

Mr. F. J. STEWARD showed a case of Excision of Epithelioma of Lower End of Pharynx. The patient, a woman aged 40, was admitted into Guy's Hospital on July 3rd, 1911, with a three months' history of pain and difficulty in swallowing. She could take fluids only, and these with difficulty. Endoscopic examination on July 4th revealed a growth involving the anterior and left lateral aspects of the extreme lower portion of the pharynx. Nothing could be felt externally, and there was no evidence of glandular infection. July 11th: Angular incision, transverse limb over thyrohyoid membrane on left side, longitudinal limb downwards along left sterno-mastoid. Depressor muscles, thyrohyoid membrane, superior cornu of thyroid cartilage, and left lateral wall of pharynx divided. From this point the anæsthetic was administered through a tracheotomy tube passed into the upper opening of the cocainised larynx, the tube being packed round with a gauze strip. The extent of the growth could now be examined with the finger; it was found to be quite small, involving principally the anterior and left lateral walls of the lower end of the pharynx and the upper portion of the œsophagus, and freely moveable on larynx and trachea. In order to give further access during the remaining stages of the operation the left lobe of the thyroid gland was then removed as it was slightly enlarged. By tilting the larynx over to the right and drawing the sternomastoid and carotid sheath backwards the site of the growth was brought well into view. The growth, which was about the size of a sixpenny-piece, was excised, together with a margin of healthy tissue about three-quarters of an inch wide. This involved the removal of the whole circumference of the œsophagus with the exception of a narrow strip of its right posterior wall, and exposed most of the posterior surface of the cricoid cartilage and the upper three rings of the trachea. Catgut sutures were then used to bring together the thyrohyoid membrane, the upper part of the pharyngeal incision, the muscles, and the transverse limb of the skin incision. A soft rubber feeding tube was then passed from the lateral incision into the œsophagus, fixed in position by a suture, and packed round with gauze. The patient stood the operation fairly well, but she was rather collapsed, no doubt owing to previous semi-starvation. She made good progress, the wound being kept sweet by daily dressing and syringing with hydrogen peroxide. August 3rd: Tube removed and replaced by one passing through the nose, the wound in the neck being allowed to granulate. This tube was kept in place for ten days, and as the wound was then nearly closed the patient was allowed to take food naturally, bougies being passed daily. Trouble then began owing to difficulty in keeping the stricture dilated, and on several occasions anæsthetics were needed in order to pass a bougie. Finally, as the stricture rapidly contracted in spite of all attempts to keep it dilated, and swallowing became extremely difficult, Mr. C. H. Fagge reopened the upper end of the œsophagus through the neck and passed a tube. Hoping that the continual swallowing movements would dilate the pharynx above the stricture, the patient was sent home on Oct. 10th. She was readmitted on Nov. 2nd, and endoscopic examination then proved that considerable dilatation had taken place, and after some little trouble a bougie was forced through the stricture, which was then dilated and a rubber tube passed through it from the nose and left *in situ*. The patient bore the inconvenience of the tube for ten days, when it was removed. From this time no further trouble had been experienced, the stricture having been kept dilated by passage of bougies. This was done three times a day at first, and the frequency gradually diminished, so that when she left the hospital on Dec. 10th she was having a No. 18 bougie passed once every two days.

and this she had continued to do herself since. The section of the growth which was exhibited showed it to be a typical epithelioma. The growth was removed as described, without sacrificing the larynx and without removal of glands, because it was clearly very recent, and, moreover, its free mobility on the underlying structures led Mr. Steward to hope that it was in the primary stage, so that local removal would give a fair chance. He would call attention to the extreme importance of not closing the wound after operations upon the pharynx. This method of wound treatment, although perhaps less artistic, was much the safer, for in this way the risks of secondary hæmorrhage and septic infection of the air passages were reduced to a minimum. The plan of administering the anæsthetic through a tube inserted into the cocainised upper opening of the larynx had proved very useful in these cases; it was quite convenient and satisfactory, and, moreover, avoided the risks associated with a tracheotomy opening. There was no sign of œdema of the glottis afterwards, although the mucous membrane was divided close to the arytenoids. The way in which the stricture was overcome by allowing the lower end of the pharynx to dilate was very striking, the extra amount of mucous membrane so formed being evidently sufficient to bridge the gap caused by the operation, as there has been no further difficulty since the final communication with the œsophagus was made.

Dr. FREDERICK LANGMEAD showed a case of Anomalous Œdema. The patient, a girl aged 18, since the age of 12 had suffered from an unexplained œdema. It began in the legs, the left being affected first. This leg had been encased in plaster-of-Paris at that time, and afterwards put up in a Thomas's knee-splint. There was no record to show why this was done, but the patient said that it had never been painful. When the plaster was removed the swelling recurred and was unaffected by splinting, but, on the contrary, a similar swelling began in the other leg. The ankles were affected first. She came under the exhibitor's observation in March, 1910, for a similar condition of the hands, at first in the left and shortly afterwards in the right. In the hands the swelling started on the dorsal aspects. The condition then found had persisted, but fluctuated considerably in intensity. Symmetrical œdema of all four limbs was present, accompanied by blueness, coldness, and sweating. The œdema was most marked in the legs and usually was confined below the knees, but had extended above on one or two occasions. Sometimes pitting could not be obtained by pressure; at other times firm pressure caused it. As in the legs, so also in the arms the œdema was most pronounced at the distal extremities. It lessened if the parts were raised, and increased if they were allowed to hang down. It was almost or completely absent in the morning, but gradually increased during the day, especially if the patient stood much. The dependent position of the arms during a washing-day was always followed by considerable swelling of the hands. The blueness was intensified by cold, to which she was very susceptible, but no sequence of events as occurs in Raynaud's disease was detectable. No redness, throbbing, or burning (suggestive of erythromelalgia) had been noted. The hands and feet were always clammy, not infrequently beads of sweat standing out from the skin, and were cold at the same time. Recently she had complained of swelling of the cheeks after meals, which subsided in an hour or so. She was very prone to septic sores. Any slight injury produced a sore, which exuded clear fluid freely, and a sodden, indolent ulcer resulted which healed with difficulty. Reddish-purple swellings had occurred occasionally in the œdematous regions, looking like chronic abscesses. A few of these had suppurated, but the majority subsided. On one occasion staphylococcus aureus, and on another a streptococcus, was isolated from the discharge. There was no sign of heart or kidney disease. The blood count was normal. The patient's general health was very good. She did her work as a general servant without trouble until the evening, when the swelling of her hands and feet caused her difficulty in holding small objects (such as a needle) and in walking. She was the only child; no history of any similar affection in the family could be elicited. The only treatment which had been beneficial was the use of elastic stockings. Thyroid extract had made no difference.

Dr. F. PARKES WEBER showed a case of Diffuse Symmetrical Lipomatosis. The patient was a man of good muscular physique, but had a number of soft subcutaneous swellings characteristic of diffuse symmetrical lipomatosis. These were situated on both sides, in the mastoid, parotid, deltoid, and inguinal regions, and also in the middle line, just below the chin, above the sternal notch, and over the symphysis pubis. They had been noticed first about four years ago, and were neither painful nor tender to palpation; neither did the patient suffer from rheumatic or other pains. The thyroid gland appeared to be well developed. The liver could not be felt, but there was a suspicion of commencing cirrhosis. The conjunctivæ over the sclerotics had a yellowish tinge. The urine (January, 1912) was of high colour, of specific gravity 1025, and free from albumin, sugar, and bilirubin. The patient had been accustomed to take much alcohol every day for years; he had severe pleurisy some years ago, and gout in both big toes about three years ago; he was subject to hoarseness; he denied having had any venereal disease, and said he had never noticed any sexual impotence; he had children living. The case was a good example of diffuse symmetrical lipomatosis occurring, as it generally does, in a man of robust build, who had been accustomed to rather free and habitual indulgence in alcohol.

Dr. PARKES WEBER also showed a case of Osteitis Deformans (Paget's Bone Disease) with Chronic Eczema. The patient, aged 70, presented the typical thickening and bending of tibiæ and femora characteristic of osteitis deformans. The disease was of only moderate degree and was limited to his lower extremities. The changes were first observed in the left tibia six years ago, and were best marked in that bone and the left femur. The eczema, to which he had been subject more or less for many years, chiefly affected his legs. The patient had enjoyed good general health usually, but had suffered twice from rheumatic fever, 40 and 20 years ago respectively. There was no history of venereal disease. Nothing abnormal could be discovered in the thoracic or abdominal viscera or in the urine. A noteworthy feature of the case was that there had been no pain connected with the bone disease.

Dr. GEORGE F. STEBBING showed a case of Persistent Nystagmus associated with periodical vomiting. The patient was aged 28. At the age of 21 he had had seven fits during one week, but had had no others. In these fits, of which he had no warning, he was unconscious and incontinent; he bit his tongue once and twice "bruised his eyes." Fifteen years ago the patient began to have pains in the lower and back part of the head, and these pains had remained since. Ten years ago one day he ate his tea with a good appetite and soon afterwards, without any feeling of sickness, vomited it; later, the same thing occurred with his supper. For several days he vomited everything he swallowed, and then regained his usual health. Ever since he had been subject to attacks of vomiting which lasted from a few days to six or eight weeks. These attacks were gradually becoming more frequent and more severe, and he stated that he had lost flesh considerably. During these attacks he sometimes felt sick, but in many of them he vomited without any sensation of sickness. Since these attacks of vomiting started he had had pain in the lower part of the abdomen; he stated that it was not relieved, but was occasionally made worse, by the act of vomiting. Three and a half years ago his friends told him that "his eyes were always moving about." Two years ago both his legs began to get weak so that he became unable to stand without support, and one year ago he "lost all feeling in them." The patient was thin, but did not appear to be markedly wasted. He had nystagmus, which was most marked while the eyes were at rest, and was of a mixed type, consisting of coarse horizontal movements with a fine rotatory movement superadded. The nystagmus was present in all positions of the eye, but was more marked when the patient was looking to the left than to the right, and was only slightly marked when he was looking up or down. There was a slight degree of hippus. The fundi were quite normal. The patient could read small newspaper print; he got tired after reading for about half an hour. There was marked loss of power in both legs, but very little wasting. Knee-jerks were present; the plantar reflexes were sluggish, but when obtained were both flexor. There was anæsthesia of both legs of the "stocking type." The Wassermann reaction was negative, and large doses of potassium iodide combined with mercury, administered for a period of six weeks, did not produce any change in the patient's condition.

Dr. HECTOR MACKENZIE and Mr. W. H. BATTLE showed a case of Hirschsprung's Disease: Congenital Dilatation of

the Colon. The patient, a girl, aged 9, was admitted under the care of Dr. Mackenzie into St. Thomas's Hospital on Nov. 27th, 1911. When a baby she had suffered from attacks of diarrhœa. Since the age of 4, when she had broncho-pneumonia, she had suffered from constipation. A year ago the constipation was accompanied by pain and vomiting. This occurred without any relation to food. She was treated for tuberculous peritonitis. The constipation and other symptoms had increased since that time, and had been bad for five weeks, a purgative being required every other night. The pain had been very severe at times, the child having been doubled up with it. On admission moderate distension of the abdomen was present, more marked on the left than on the right side, and most evident in the upper part. On inspection, particularly after palpation, slow waves of peristalsis were seen, most marked in the umbilical region, and seeming to travel from left to right, but also present over the descending colon and passing downwards, but without pain. A tympanitic note was obtainable all over the abdomen. Occasional attacks of pain accompanied the peristalsis later, occurring nearly every day, but varying in time of onset. The abdomen generally was larger than normal and the sigmoid was easily felt. X ray examination after giving a bismuth meal showed that it all went to the right side just above the iliac crest. Four days later, there having been one action of the bowels, there was still some bismuth low down in the mid-line of the pelvis.

Dr. HERBERT FRENCH showed a case of Tabes Dorsalis with one Knee-jerk Absent and the other Brisk. The patient had gonorrhœa when aged 16, for which he was treated for six weeks at St. Thomas's Hospital, but was not aware of having had a chancre. His wife had had one miscarriage, but no living child. The Wassermann reaction was positive. Five years ago he suffered from pain in his right foot, spreading thence to the right ankle, and after a few weeks upwards into the calf of the right leg; since that time he had been subject to shooting pains which were confined to the right leg, never affecting the left, and at the same time whilst the left leg felt to him normal, the right had become numbed, cold, and affected by a feeling which he described as one of uselessness, although objectively he could move it very well. Perhaps the most striking feature about the case was the fact that whereas the right knee-jerk was entirely absent, the left was not only present but was even brisker than normal.

Mr. BATTLE showed a case of Neuro-fibroma of the Supra-orbital Nerve in the Orbit.

Dr. WILFRED HARRIS and Mr. W. H. CLAYTON-GREENE read a paper on a case of Congenital Absence of the Left Half of the Diaphragm, simulating Pneumothorax.

LARYNGOLOGICAL SECTION.

Exhibition of Cases and Specimens.

A MEETING of this section was held on Feb. 2nd, Dr. STCLAIR THOMSON, the President, being in the chair.

The following cases and specimens were shown:—

Mr. HERBERT TILLEY: 1. A Specimen and Section of Discrete Angioma of the Nose, which had been removed from a young man, aged 17, who applied to hospital for severe attacks of nose bleeding, which had rendered him very anæmic and weak. 2. A case of Enlargement and Distension of the Bridge of the Nose in a patient suffering from Nasal Polypi and Pansinusitis. The upper regions of the septum were also thickened and considerable periostitis of the bones seemed to be present.—The PRESIDENT, commenting on the appearances, remarked that in the cases he had seen, as in the present case, there had been no evidence of syphilis.

Mr. J. EVERIDGE: A case of Ulcerated Growth of the Larynx with a Negative Wassermann Reaction.—In the opinion of most of the members the disease was regarded as a tuberculous deposit.

Mr. C. A. PARKER: A Thyroid Tumour at the Base of the Tongue in a girl, aged 16 years. The tumour was so large as to call for removal, but the apparent absence of any thyroid gland in the neck had led to hesitation in operating. The suggestions offered by members to avoid the difficulty were that the tumour might be dislocated from its buccal site to a position deeper in the tissues of the tongue, or that a partial excision only should be made.

Dr. W. H. KELSON: A Swelling in the Right Tonsillar Region in a woman, aged 24, with a hard mass at the angle of the jaw. The swelling also involved the lateral pharyngeal region above and behind the tonsil. The disease was generally regarded as inflammatory, possibly originating in a chronic suppuration of the ear from which the patient was suffering.

Dr. ANDREW WYLIE: A case of Paralysis of the Soft Palate dating from a sore throat several weeks previously. Repeated bacteriological examinations had failed to disclose the presence of the Klebs-Löffler bacillus, and several of the speakers referred to the elusive character of this organism as a fact which renders a negative finding of no value.

Dr. G. WILLIAM HILL exhibited a series of skiagrams illustrating (*a*) the palliative action of radium salts in malignant stricture of the gullet; and (*b*) the advantages of the X rays screen for accurately applying a radium apparatus in the strictured area.—Mr. TILLEY and the exhibitor drew attention to the importance of the necessity for the nicest precision in introducing and leaving radium in the œsophagus in cases of malignant stricture.

Dr. JAMES DONELAN: A singer, aged 44, with a growth on the Anterior Third of the Right Vocal Cord, which was regarded as a singer's node.

Mr. CHARLES W. M. HOPE: A microscopical section of a Malignant Columnar-celled Carcinoma of the Œsophagus from a man, aged 25 years. Attention was drawn to the occasional appearance of a columnar-celled cancer in a tube lined by squamous epithelium, and the mode of origin of such growths was adverted to.

Mr. NORMAN PATTERSON: A case of Abeyance of Nasal Breathing of Hysterical Origin, the speech being markedly affected.

Dr. E. A. PETERS: 1. A case illustrating the formation of Bilateral Symmetrical Perforations of the Palate in a case of syphilis. 2. Another case of Tumour of Right Lateral Wall of the Pharynx involving the Right Arytenoid in a woman, aged 27 years.—The advisability of the early examination of such cases by the direct method in order to exclude post-cricoid carcinoma was remarked upon.

Dr. G. C. CATHCART: A case of Sublingual Ulceration of the Floor of the Mouth.—It was considered by certain of the members to be septic in origin.

Mr. G. SECCOMBE HETT: A series of three cases illustrating Cysts of the Larynx. In one the cyst lay on the lingual aspect of the epiglottis; in the second on the vocal cord; while in the third a cyst, or cystic fibroma, was to be seen on the right arytenoid.—Discussing the treatment of laryngeal cysts, several members expressed a preference for the galvano-cautery as compared with their removal by means of forceps.

Dr. J. DUNDAS GRANT: A woman, the subject of Tuberculosis, with an outgrowth from the lower pole of one tonsil.

SECTION OF ANÆSTHETICS.

Chloroform Poisoning.

A MEETING of this section was held on Feb. 2nd, Dr. W. J. MCCARDIE, the President, being in the chair.

Dr. R. S. FREW, in a paper on the Significance of Acetonuria in Children, showed that acetonuria was produced in the child by mere changes of diet; further, that the duration of the acetonuria was about three days, that it was more marked the younger the child, being 100 per cent. in babies changed from breast to artificial feeding and 46 per cent. in children 11 and 12 years of age, the average of all children below 12 years of age being 61 per cent. He further pointed out that by giving dextrose this acetonuria could be made to disappear at any stage within 12 hours, and that the carbohydrate starvation necessary for its production was caused by the digestive instability of children. He drew attention to acetonuria being invariably produced by gross starvation in about 12 hours. It was maintained that both these conditions obtained in the preparation of the child for anæsthesia, and that this was sufficient to account for the high percentage of acetonuria *after* anæsthesia recorded by various observers, which ranged from 63 to 89 per cent. Dr. Frew pointed out that this acetonuria could be prevented by the administration of dextrose up to and after the administration of the anæsthetic, thus avoiding what must be regarded as an additional risk.

A paper was read from Dr. A. L. M. MUSKENS, of Bergen-op-Zoom, Holland, describing the results of some experiments

on rabbits, made to investigate the after-effects of chloroform. Twenty-five rabbits were kept under chloroform for from one to two hours. Tables were shown illustrating the tissue changes in eight rabbits which died from the effects of the anæsthetic at periods of from 22 to 100 hours, and in eight others which were killed at periods of from three hours to five days after the administration. In the first group all the cases, except one where chronic myocarditis was the cause of death, showed advanced fatty degeneration of the liver amounting in most instances to complete central necrosis; in the rabbits in the second table (except in one case killed immediately after the operation) fatty degeneration was also found, but to a somewhat less-advanced degree than in the first group. Changes in the kidney and heart tissues were much slighter and more variable. Dr. Muskens considered that the liver degeneration was due to the chloroform and was the cause of death in the fatal cases. He suggested that fat and oil should be avoided before an anæsthetic, either in food or drugs, and that cholagogues might be useful afterwards in so far as they tend to remove fat as well as bile from the liver.

Mr. R. E. APPERLY showed some microscopic specimens from livers of rabbits and also of human subjects illustrating the after-effects of chloroform. The rabbits had been kept under chloroform for half an hour daily for several days, and subsequently killed; in one of the human cases the patient had had two anæsthetics at a short interval, the first ether, the second chloroform; he died shortly after the second administration from cerebral hæmorrhage unconnected with the operation or anæsthetic. All the specimens showed fatty changes. Mr. Apperly pointed out that acetonuria occurs after anæsthesia in nearly all cases; after ether the amount is much greater, but falls to the minute trace which may be considered normal in one day; after chloroform the rise is less, being as 20 to 50, but persists in a gradually diminishing degree for four days. This was doubtless to be explained by the fact that chloroform has much more effect upon the kidney than ether and delays excretion. In severe post-anæsthetic vomiting little acetonuria is generally present; when the vomiting stops the acetonuria increases.

Dr. A. L. FLEMMING agreed with the last speaker in regard to the respective effects of ether and chloroform upon the kidney. He stated that in 68 cases where careful examination of the urine had been made far more kidney cells were found after chloroform than after ether, and fatty changes were also present. Acetonuria frequently existed in cases where there was loss of fluid—i.e., vomiting—and he found that where a previous injection of saline had been given there was generally little acetonuria or unpleasant after-effects.

The PRESIDENT read notes of a case of Chloroform Toxæmia after an operation for Cleft Palate on a child aged 2½. The operation was difficult and lasted one and a quarter hours. The anæsthetic was borne perfectly and but little blood was swallowed. At night the child was much collapsed and remained seriously ill all next day, but gradually improved. The palatine flaps sloughed. The same child had had an operation when 12 months old, which was followed by prolonged vomiting. It was noteworthy that this child could not tolerate fat in any form. Cod-liver oil invariably upset him and starchy foods had the same effect. He was subject to attacks of "liver-chill," accompanied by vomiting and diarrhœa. At a subsequent operation ether had been administered for half an hour with no after-effects.

Dr. J. H. THURSFIELD referred to a series of post-anæsthetic deaths which had occurred at the Hospital for Sick Children, Great Ormond-street, in 1907, the causation of which was still under investigation. These deaths occurred under varying conditions and were not to be explained either by the anæsthetic used, the methods of administration, or the preparation of the patient. He thought there was an additional factor still to be discovered. Acidosis occurred in all cases, and in a few passed into acid intoxication. Children operated on in the out-patient room, whether prepared or not, showed reaction next day in 100 per cent. of the cases. Those operated on four or more days after admission were not found to react differently from those operated on immediately. He considered that dextrose had no effect whatever on acid intoxication. Sodium bicarbonate gave better results. He did not believe that the condition of the liver was causative or peculiar to the condition under discussion. The same changes were found in many diseases with quite different symptoms.

Dr. G. W. GOODHART did not agree that the liver changes found in acid intoxication were the same as those in other diseases. He thought that the clear differentiation of three zones was characteristic and not found in other conditions. He doubted whether there was any fatty degeneration of the kidney; this was difficult to prove as fat occurs in quite healthy kidneys.

Mr. G. E. WAUGH objected to the name post-anæsthetic poisoning. None of the cases referred to above had occurred among his cases, and he attributed this largely to his method of preparation. He had abolished purging and preliminary starvation, merely substituting the operation for a meal. He gave a large dose of soluble carbohydrate both immediately before and after the operation. He considered dextrose better than sodium bicarbonate, and instanced two cases where the patients' lives had apparently been saved by the use of the former.

Dr. J. F. W. SILK agreed with Mr. Waugh that the name should be dropped. Post-operative acetonuria depended on a complicated series of conditions. He thanked the members of the staff of the Hospital for Sick Children for their kindness in giving valuable information to the section.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A pathological meeting of this society was held on Feb. 2nd, Mr. W. McAdam Eccles, the President, being in the chair.—After the formal opening business of the meeting the President proposed that a vote of condolence should be sent to Lady Butlin on her recent bereavement. As a society they felt that loss, for Sir Henry Butlin had been for many years a member with them, and they had recently elected him an honorary member.—The President showed a number of specimens of so-called "Dermoid Cysts" of the Ovary, all of them exhibiting the presence of teeth. He discussed their probable origin, whether they were true teratoma, an epithelial inclusion, or a kind of unisexual development. He inclined to the first hypothesis.—Mr. Aslett Baldwin showed a specimen of Teeth from an Ovarian Dermoid in which the number and perfection of the teeth were remarkable.—Mr. Hopewell Smith, in commenting on these specimens, said that microscopic examination of these teeth usually showed that the hard tissues were mal-formed and the dentinal tubes irregular in arrangement.—Mr. Aslett Baldwin showed, amongst other specimens, a radiograph of Fractured Neck of a Femur with screw uniting the bone in position. The case was that of a man, aged 40 years, who fell from a cart. The fracture caused a shortening of two inches. The shortening was reduced by an apparatus which permitted screw traction on the limb, and when perfect length had been secured the steel screw, shown in the radiograph, had been driven through the trochanter into the neck and head of the bone. The whole was secured by a plaster mould.—Mr. Walter E. Fry showed a Decidual Cast from a case of Extra-uterine Gestation. A multipara, aged 26, missed one period. A fortnight later there was sudden violent pain about the left ovary. She was examined under chloroform but nothing abnormal was found. A week later the cast was passed and she recovered. Sections of the cast showed decidual cells of maternal origin but none of fœtal origin. Mr. Fry asked if there was a conception, where was the fœtus?—There was a discussion on this case in which Dr. H. J. F. Simson, the President, and Dr. Julius M. Bernstein took part.—Dr. Bernstein showed a number of specimens of recent cases of fatal visceral disease. Some of these led to valuable discussions. One was a case of Acute Infective Endocarditis in a man aged 40. The patient had been seen by Dr. L. C. T. Dobson, who said that the man's first medical attendant had considered the case one of cerebro-spinal meningitis; ten days later the medical man fell ill with the same symptoms. Dr. R. J. Reece, of the Local Government Board, inclined to the same diagnosis, but examination of fluid obtained by lumbar puncture in both cases proved that both were suffering from pneumococcic infection. The man died and the medical man recovered. Dr. Bernstein considered endocarditis was a late secondary lesion, for there were no heart symptoms pointing to it.—There was shown for Mr. L. A. Bidwell Masses of Soft Fibroma or Fibro-lipoma, which formed a retro-peritoneal tumour; the symptoms pointed to the presence of a hydatid.—The President said that diagnosis of these cases was difficult, and that occasionally the growth

attained a huge size.—Dr. Bernstein showed a film preparation of pure Klebs-Löffler Bacillus taken from a case of Membranous Rhinitis.—Dr. F. G. Crookshank said that these cases were not uncommon, although rarely recognised except by nose specialists. The symptoms and sequelæ were not severe as a rule; he thought that was due to the absence of mixed infection.—Dr. A. C. D. Firth showed a specimen of Ulcerative Endocarditis, due to general pneumococcal infection, in a child aged 3 The examination of hospital reports for nine years only showed the occurrence of one other similar case at this early age.—Dr. Reginald Morton showed skiagrams of cases examined with other physicians. One, with Dr. H. Pritchard, was of a case of Aneurysm of the Arch of the Aorta; the shadow of the aneurysm and the obstructed mass of a bismuth meal in the œsophagus could be seen. Other plates were of a case of Gastroptosis, under the care of Dr. Bernstein. The progress of the bismuth meal in its various stages was shown, and the site of the delay noted.—Dr. Simson showed cases illustrating the difficulties to be met with in the diagnosis of cancer of the uterus. There was a typical cauliflower growth of the cervix in which diagnosis was unmistakable; one of intra-cervical growth of most malignant character, but causing few symptoms; another of a uterus removed in a case of pyometra and grave symptoms simulating carcinoma of the body of the uterus, all of which were due to a fibroid in the posterior wall causing obstruction.—Dr. E. A. Saunders and Mr. Bidwell showed a specimen of Pyloric Ulcer removed by partial gastrectomy with excellent results.—Dr. Alfred Eddowes showed photographs illustrating diseased conditions of the nails: (1) Psoriasis; (2) Overgrowth and Deformity of the Great Toe Nails due to Injury; and (3) a Rare Condition of the Nails of Hands and Feet that had been thought to be Ringworm.

LIVERPOOL MEDICAL INSTITUTION.—A meeting of this society was held on Feb. 8th, Mr. R. Jones, the President, being in the chair.—Dr. J. Hill Abram read a note on two cases of Œdema of the Orbit. The first case was a man, aged 30, who had swelling in the neck and in the right orbit, a naso-pharyngeal discharge of muco-pus, and just before death a violent epistaxis. A post-mortem examination showed necrosis of the pituitary body, with enlargement and œdema of the lymphatics of the right side of the neck; no growth was found, and the tissues were not further examined. The second case was in a robust man aged 53. His illness began with pain in the right temple, swelling in the right eye, and a rise of temperature. The orbit was incised. At the post-mortem there was exudation at the base of the brain, pus in the cavernous sinuses, thrombosed veins, and an actinomycotic mass in the orbit. Two difficult points to decide were: how the organism gained access to the body, and what was the source of the infection. The mouth, teeth, and the intestinal canal, and even the skin, had been suggested as points of entry. The infection might come from domestic animals or from foreign bodies, such as straw or splinters of wood. As the organism was found in carious teeth it was possible that it led a saprophytic life. Dr. Abram suggested that further investigation was needed to decide whether the organism was anaerobic in man and aerobic in nature. He could find no conclusive evidence of infection from man to man or from cattle to man.—In the discussion that followed Dr. J. Lloyd Roberts mentioned a case of œdema of the orbit with œdema of the rectum, in which an organism similar to the bacillus of diphtheria was found. The patient was given anti-diphtheritic serum, with the result that the swelling began to disappear in 15 hours, and in a few days the patient was quite well.—Mr. C. A. Adair Dighton referred to a case of actinomycotic meningitis following excision of the right eye for panophthalmitis after injury. In this case there was no œdema of the orbit.—Dr. C. O. Stallybrass suggested milk as a vehicle of infection, as the disease had been found in the udder and the organism in milk.—Dr. Lloyd Roberts opened a discussion on Colitis from the medical side. He reviewed our knowledge of the subject, and especially referred to Dr. Hale White's investigations, which began about 24 years ago. Dr. Lloyd Roberts commented on the increase in frequency of the disease as well as of appendicitis since then.—Mr. F. T. Paul opened the discussion on the surgical side. He used two operations—appendicostomy for the milder cases and right lumbar colotomy for the more severe. A small incision gave access to the appendix; its base was anchored by fishing-gut sutures, and a narrow rubber tube or pointed catheter was passed into the colon at the first operation. If left to a later stage difficulty might be found owing to the shrinkage which took place in the appendix. Right lumbar colotomy was a difficult operation; opening the peritoneum did not much matter but it was important not to undermine it or injure the duodenum. He did not make as much of a spur in these cases as in other colotomies. He began systematic washing out of the bowel about two weeks after the operation and did not find that antiseptics made much difference.—In the discussion that followed Dr. T. R. Bradshaw claimed for castor oil in small doses an almost specific action in cases of colitis.—Dr. S. M. Whitaker spoke of the treatment by electric enemata, by lactic acid cheese, and by enemata of allantoin.—Mr. R. W. Murray said that in the first wash-out it was important not to use a larger quantity of fluid than half a pint, as large amounts sometimes caused collapse.—Dr. C. J. Macalister spoke of the connexion between colitis and rheumatoid arthritis. Common paraffin had been found useful as it formed a coating in which organisms could not live. He had found simaruba and pomegranate bark useful in these cases.—Dr. C. L. Williams, Mr. G. P. Newbolt, Mr. Colin G. Campbell, Dr. D. Moore Alexander, and Dr. O. T. Williams took part in the discussion.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Feb. 2nd, Dr. A. Freeland Fergus, the President, being in the chair.—Lieutenant-Colonel Sir William Leishman, R.A.M.C., delivered an address on Anti-typhoid Inoculation. After reviewing the history of the subject, the speaker referred to various methods of preparing anti-typhoid vaccine, and described that employed in the British Army. The strain of typhoid bacilli used was one the virulence of which had by long culture been greatly diminished. From sub-cultures of this strain, grown for 36 hours and killed by exposure for an hour to a temperature of 53° C., the present vaccine was prepared. Careful tests were made to ensure the sterility of the vaccine before its issue for use, and no instance had occurred of sepsis attributable to it. Standardisation of the vaccine was effected by counting the number of bacilli present along with a known quantity of normal blood the plasma of which had been replaced by saline solution. The doses usually given were an initial dose of 500,000,000, and, ten days later, a second dose of 1,000,000,000 of dead bacilli. If a single dose only could be given it was one of 1,000,000,000. Experience in England and in India quite dispelled the idea that owing to the development of a negative phase, with increased susceptibility to infection, persons inoculated in presence of an epidemic of enteric fever ran more risk than the non-inoculated of contracting the disease. On the contrary, inoculation proved highly protective. As to the conditions under which anti-typhoid inoculation ought to be carried out as a prophylactic measure, in civil life all persons in attendance on cases of enteric fever and, on the occurrence of enteric fever in any large institution, all the inmates should be inoculated. In the army, even in time of peace, enteric fever was certain to be introduced either by recruits (typhoid carriers or men incubating the disease) or from the surrounding population; and in time of war even the best sanitary organisation was powerless to ensure protection from infection. All recent military experience showed the enormous incidence of invalidity and very high death-rate from this cause. The benefits resulting from anti-typhoid inoculation were strikingly shown by the statistics of enteric fever among British troops in India. For 15 years prior to 1907 the annual number of admissions had averaged 1406, with an average of 353 deaths. In 1905 anti-typhoid inoculation was introduced as a voluntary measure, and while at first not largely utilised, was by 1907 being taken advantage of by the troops in increasing numbers. Since that date the admissions from enteric fever had fallen steadily till in 1910 they numbered only 296, with 45 deaths. Recent experience with a large body of United States troops stationed on the Mexican frontier, among whom anti-typhoid inoculation was compulsory, proved the almost complete protection which this measure afforded the soldiers. Many observers had also found that anti-typhoid inoculation was of value, not only in prophylaxis, but also as a therapeutic agent in cases of enteric fever, and the speaker believed that for this purpose a stock vaccine was more effective than an autogenous one.

Reviews and Notices of Books.

Prehistoric Man. By W. L. H. DUCKWORTH, M.A., M.D. Cantab., Sc.D. Cambridge: The University Press. 1912. Pp. 156. Price 1*s.* net.—This little book is one of the Cambridge Manuals of Science and Literature, issued by the University Press under the general editorship of Dr. Giles, the learned master of Emmanuel College, and Professor Seward, the professor of botany in the University. It displays the arguments to be relied upon in speculation upon the origin of the human race, and in its closing chapter, which takes note of the bearings of recent discoveries, the conclusion is reached that up to a certain point the evidence is strikingly favourable to the hypothesis of evolution, defined as "the gradual development of the modern type of skeleton found in association with a large and active brain capable of manifesting its activity in a great variety of ways." The time factor, as the author points out, is the greatest difficulty as yet which those who want to make definite statements have to face, and he illustrates the risk of forming conclusions on the subject by noting that in 1904 Professor Rutot assigned a duration of 139,000 years to the Pleistocene period, while five years later Dr. Allen Sturge claimed 700,000 years for a portion only of the same period. We recommend this admirable little manual to all our readers, and not only to those who take a practical interest in palæontology, for any medical man may find himself actually in need of practical information on the subject now that excavations, accidental as well as purposeful, are becoming fruitful. Much of the material evidence upon which the theories concerning the human pedigree are based consists of detached skeletal fragments; the more of these that come to light the greater grows the chance of filling up the immense lacunæ in our knowledge of the human pedigree; and no one is so likely as the medical man, usually the only anatomist in the community, to be able to indicate how far any discovery of bones has a genuine historic bearing.

Who's Who in Science (International), 1912. Edited by H. H. STEPHENSON. London: J. and A. Churchill. Pp. 323. Price 6*s.* net.—This book may be described as an endeavour to fill to some extent among English books of reference, for scientific workers and others, the place as a handbook of the international academic world that is occupied in German by the well-known *Minerva*. It contains a tabular list of the world's universities, with the names of their senior professors (only) in the various faculties of the natural sciences, pure and applied, and a biographical directory of all who have academic office. The objective sciences alone are dealt with, the humanities and such borderland branches of knowledge as economics, sociology, psychology, education, and exploration being excluded, though the names of many of the leaders therein appear, inasmuch as their work often overlaps the natural sciences. The list of the world's universities is meagre, only 134 being given. This list does not include a single one of the universities in South America, there are many omissions of universities in the United States, and important European universities also are left out. It is not clear whether the note, stating that "any omissions in this list are due to the university in question not replying to our communication," is intended to cover the absence of all reference whatever to certain universities, or merely to account for certain lacunæ in the information given as to the *personnel* of some of the universities that are included in the list. But even in the latter case we note the omission, in the biographical part, of names which appear in their proper places in the university tables, whose owners have certainly done work that, in our opinion, should entitle them to a place in the biographical part. We welcome the book, however, as an instalment of a work that has long been needed, which we have no doubt will be brought more fully up to date with each succeeding issue.

Some Factors Influencing Health in Tropical and Subtropical Countries. By T. GERALD GARRY, M.D., M.A.O., M.Ch.R.U.I. London: John Bale, Sons, and Danielsson, Limited. 1911. Pp. 96. Price 2*s.* 6*d.* net.—This small handbook should prove of interest to travellers and others about to journey in the tropics or to those already residing in those regions. The work is subdivided into four sections. The first deals with general considerations and bacillary and parasitic diseases, and discusses the type of man and woman suitable or otherwise for residence in tropical countries. The causes of tropical disease and the food and drinks to be used in warm countries are passed in review in the second section. Recommendations with regard to clothing, exercise, and ablution form the more important subject matter of the third section, while the prevention of disease is discussed in the last. The author states that the contents of the handbook have already appeared as a series of articles, and at the request of some friends interested in tropical hygiene he has been induced to publish them in their present form. The work is dedicated, by permission, to Lord Kitchener.

Guide to the Pathological Specimens of the Organs of Generation in the Female, Museum Royal College of Surgeons. By ALBAN H. G. DORAN, F.R.C.S. Eng. Illustrated. London: Taylor and Francis. 1912. Price 6*d.*—This guide has been compiled by Mr. Alban Doran to assist visitors to the Museum who make use of the series illustrating diseases and injuries of the female organs. While the catalogue is mainly devoted to analytical descriptions of individual specimens, the Guide consists of a summary of general pathological conditions, and indicates how they are illustrated by the individual specimens. The Guide is illustrated by some good figures taken from various sources, and it forms an interesting *résumé* of the contents of this portion of the Museum.

Nisbet's Medical Directory, 1912. In two parts. Part I., Directory of Medical Practitioners. Part II., The Local Directory. London: James Nisbet and Co., Limited. Pp. 906. Price 8*s.* 6*d.* net.—Nisbet's Medical Directory this year appears with two marked improvements. In the first place it is printed on better paper and in clearer type, and in the second the Christian names are given in full, instead of by initials only. The importance of this last point only those who have to identify a particular unknown medical man out of a group all bearing the same patronymic and not infrequently the same initials can appreciate. There is much to be said in favour of a purely alphabetical directory also.

Cocoa and Chocolate: Their Chemistry and Manufacture. By R. WHYMPER. London: J. and A. Churchill. 1912. Pp. 327. Price 15*s.* net.—How remarkable has been the growth of the cocoa industry since the cacao bean was introduced into Europe in 1528 by Cortes, the conqueror of Mexico, is made interestingly evident in Mr. Whymper's "Cocoa and Chocolate: Their Chemistry and Manufacture." This is a comprehensive work dealing with every stage in the production of cocoa from the time that the bean is plucked from the cacao tree to the point at which it becomes finished powder—cocoa, as the public know it. Analyses are furnished of the cocoas upon the market, as well as of the changes which the raw material undergoes at various stages of its manufacture, those, for example, which occur during fermentation, drying, and roasting. The story is a very interesting one, and now that cocoa has become an important

and a favourite article of food in the daily diet, besides forming the foundation of a universally appreciated and wholesome sweetmeat, it is desirable that we should possess an authoritative book of reference upon the subject. We should like to have heard from Mr. Whymper something more about the alkalinity of cocoas. He seems to conclude that because the ash of ignited cocoa is alkaline alkali is added. We have found in certain Dutch cocoas no free alkali at all, but the ash was excessive and strongly alkaline. This suggests the addition not of alkali, but of organic salts, which burn into alkaline carbonates.

JOURNALS AND MAGAZINES.

Jahreskurse für Aerztliche Fortbildung. Munich: Lehmann. Price 16 marks per annum.—The November number of this Annual Post-Graduate Medical Course is devoted to a consideration of the diseases of the special senses, eye, nose, and ear. It is, of course, difficult to adapt a general review of medical progress to these subjects. Either so much detail will be given that the general practitioner is bewildered, or so little that the article is useless to the specialist. The authors of the present number have merely selected a few subjects in each specialty, but even with this limitation there are so many things treated of in such a short space that the whole is less useful than other numbers of this most valuable journal.

Professor L. Bach, who writes about sympathetic ophthalmia and squint, holds that the modified ciliary nerve theory of Schmit-Rimpler best explains the former condition. That is to say, it is the reflex result of ciliary nerve stimulation by the exciting eye, and this causes a disturbance of circulation which lays the sympathising eye open to the attack of infective material. In this process, too, anaphylaxis is held to play an important part. Whilst removal of the exciting eye is the only remedy, large doses of salicylates are regarded as having some power to avert the disaster. In speaking of squint, the author gives the teaching now current in most English text-books. Correction of errors of refraction is to be sedulously pursued in the first years of life, and operation resorted to only after the tenth year, when glasses have failed to cure. Advancement operations are more highly commended than tenotomies. In divergent strabismus an operation is usually necessary because nerve factors are much more important than errors of accommodation in its origin. Professor von Eicken writes about diseases of the nose and discusses the recent advances in diagnostic methods, especially in the use of adrenalin preparations to cause shrinkage of the vascular mucous membrane, and the demonstration of the varying conditions of the air cells by means of the X rays. The innumerable modifications of the operation of submucous resection of the septum are regarded as evidence of the inexperience of their authors. Operation is said to be very rarely required in the acute stage of sinus suppuration, and much less often in chronic stages than is generally practised. Professor Werner Kümmel writes about diseases of the outer and middle ears. The relation of otitis to general infections—e.g., pneumonia, meningitis, and diphtheria—is discussed, and it is urged that it is often merely a part and not the cause of such a general infection. He gives a short but most useful account of the various inflammatory conditions of the middle ear and mastoid, with their appropriate treatment.

The December number is devoted to general surgery and to accidents, and it forms, perhaps, the most valuable number of the whole year. Professor Payr writes about the modern position of the surgery of the stomach. And first as regards ulcers. The pathology of gastric ulcer is a subject of great complexity. Many factors are potent in its causation and usually more than one is necessary to bring it about. These may be grouped as follows: 1. Lesions of blood-vessels. Thrombosis caused by local irritation and embolus from some focus of portal infection. Sclerosis of blood-vessels with a proliferation of the intima. An area of vessels may be closed by spasm. The injections of hot salt solutions, formalin, alcohol, and adrenalin solution into the stomach vessels have caused chronic ulcers in animals. 2. Nerve lesions. Division of the vagi causes typical gastric ulcers, which show very varying tendency towards healing. 3. Chemical changes. It is a matter of uncertainty whether these are the cause or the effect of ulceration, but they certainly disappear after the excision of an ulcer. 4. Trauma and bacterial infection are very rare and doubtful causes when acting alone. 5. Toxic agencies. Appendicitis may cause either hæmorrhage from the mucous membrane or actual ulceration. 6. Anæmia. This cannot cause ulcer in the absence of other contributory factors. 7. Predisposing conditions—e.g., asthenia, enteroptosis, dyspepsia, &c. The relationship of chronic ulcer to cancer is regarded as very important. Various authors state that the proportion of cases of cancer that are derived from pre-existing ulcer is anything between 25 and 71 per cent. The locality of the ulcer is often indicated by that of the pain. Right-sided pain is due to an ulcer of the pylorus, left-sided to an ulcer of the lesser curvature, and pain in the back to an ulcer adherent to the pancreas. About 75 per cent. of cases of gastric ulcer cause occult bleeding, which can be discovered only by special examination of the vomit or motions. The delay in emptying the stomach, which is so often seen with gastric ulcer, may be the result of spasm or of stenosis of the pylorus. Examination by the X rays after bismuth feeding reveals the size, shape, and position of the stomach, and also any alteration in contour, the rapidity of emptying, the manner of peristalsis, the presence of adhesions, and the existence of hour-glass constriction; but much experience is required in the interpretation of the X ray findings. Jejunostomy and gastrostomy are of value in certain cases of rupture of gastric ulcers, for the purpose of feeding. In the latter operation a tube is passed right through the pylorus into the duodenum. In the treatment of gastric hæmorrhage atropine is of some value as it paralyses the stomach movements. In the treatment of gastric ulcer, apart from its complications, only the chronic cases require surgical interference, and excision of the ulcer or resection of the part of the gastric wall containing it is held to be superior to gastro-enterostomy.

Professor Borchardt writes about Appendicitis, referring especially to those points still in dispute. The existence of epidemic forms of the disease is regarded as not yet proved, but the prevalence of the disease at certain times and in certain places is very noteworthy. About four-fifths of all persons dying between 60 and 70 are said to show lesions indicative of a past inflammatory condition in the appendix. Figures are given for the comparison of the results of the most conservative and the most active treatment. In the former the mortality is 9 to 12 per cent.; in the latter 6 per cent. Although the second attack is much less dangerous than the first, it is quite unjustifiable to postpone operation in order to wait for an interval or a second attack. Everything points to the advantage of the early operation. It is less dangerous, there is no septic peritonitis and no complications, the wound can be closed, and there is no fear of hernia, whilst the recovery is smooth and rapid. By the early operation is meant one done within 48 hours of the onset. Towards the end of the second day the fate of the peritoneum round the appendix is decided, but it cannot be predicted

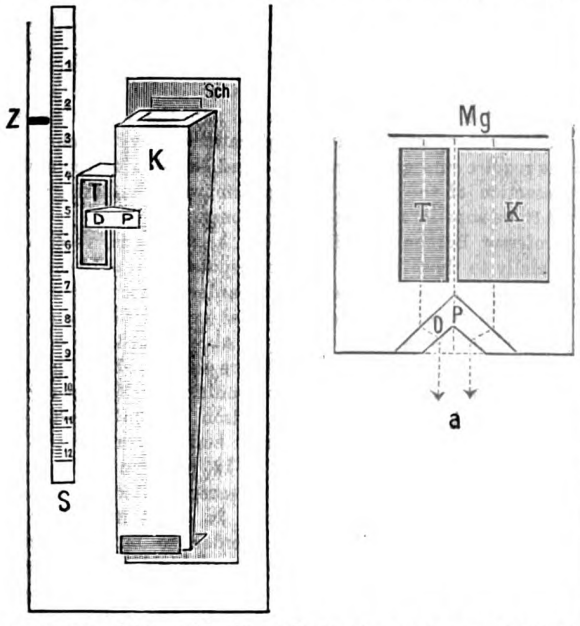
before this time. In seeing the early cases, care is required in the diagnosis from pneumonia, enteric fever, cholelithiasis, and renal calculus. Local tenderness and muscular rigidity are the signs of the greatest importance, and the presence of leucocytosis is often of value. Operation during the intermediate stage of the disease remains the most debateable question. The author holds that it is indicated only when there is distinct evidence that the patient is becoming worse, its disadvantages being the difficulty of finding the appendix, buried in firm adhesions, and of dealing with it adequately, whilst there is great risk of septic embolus and of fæcal fistula. As regards the interval operation, it is held that in the case of those aged from 40 to 45 the liability to a second attack is so slight that they may well wait without operation if they have recovered from a first attack. Late cases with peritonitis should be operated on before the distension indicating intestinal paralysis has occurred. All are now agreed that these cases require rapid and simple procedures, with removal of the appendix and closure of the parietes round the drainage-tube. The author agrees with Rehn, Korte, and Kümmell in using irrigation to flush out the abdomen in general peritonitis. He also advises the raised position of the body with the use of continuous rectal infusion of salt solution.

Professor Thiem writes a short but suggestive article on the relation of cancer and tubercle to injury.

New Inventions.

THE UNIVERSAL COLORIMETER.

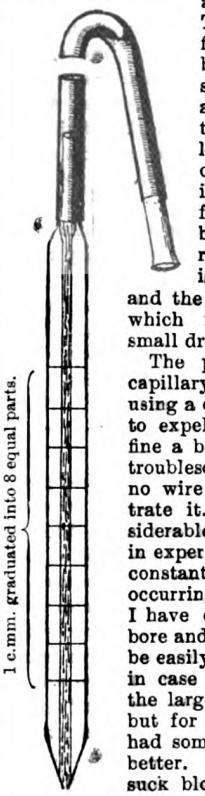
WE have had an opportunity of examining this apparatus and we think that it is one of the most compact and ingenious colorimeters we have seen. The standardisation depends upon a hollow glass wedge (K) containing the standard colour, the solution under examination being placed in a trough (T). By means of a screw the wedge can be moved up or down, and that part of it coinciding with the solution under test in the trough brought



in juxtaposition with it, and so an exact agreement in colour between the two can be arrived at. The point is registered on the scale (Z). Mg is a milk glass plate which provides the background for the colours, and D P is a double plate which serves to bring each colour into equal fields. There is no separating line between the two colour surfaces; the trough has parallel walls; the reading is done through a small slit; the wedge remains calibrated once and for all. It is applicable to the determination of hæmatin and iron in the blood, of iodine in the thyroid gland, of creatin, sugar, and indican in the urine, and a number of other reactions dependent upon the production of colour. It has also a wide application in the arts and industries in which colour is a guide to grade or quality. The universal colorimeter was exhibited to us by Messrs. F. Hellige and Co., of Freiburg in Breisgau, but we understand that it may be obtained in this country from the usual dealers in scientific apparatus.

A NEW BLOOD-COUNTING PIPETTE FOR ESTIMATING THE NUMBERS OF LEUCOCYTES AND BLOOD PARASITES PER CUBIC MILLIMETRE.

THIS pipette was devised to facilitate an extensive research on the enumeration of parasites in the blood in cases of malarial fever and sleeping sickness. The pipette is about 5 inches long and is made of glass tubing similar to that used for thermometers, with a white opal background and powerful magnifying surface. The capillary bore, however, is not flattened out like that of a thermometer, but is more nearly circular in cross section. The bore is exceedingly fine and hair-like—such that a portion of the capillary about from 60 to 70 mm. long has a capacity of 1 c.mm. This cubic millimetre length is graduated into equal parts, so that a given fraction of a cubic millimetre of blood can be accurately blown out. A rubber tube with a glass mouthpiece is attached to one end of the pipette, and the other end tapers to a very fine point, which is necessary for expelling accurate small droplets of blood. (See diagram.)



The pipette possesses about the limit of capillary fineness for blood work, because in using a capillary of less diameter it is difficult to expel the blood (which clots quickly in so fine a bore). When this clotting occurs it is troublesome to clear the pipette, as there is no wire fine enough or rigid enough to penetrate it. Even with the bore employed considerable care and practice are required; but in experienced hands the pipette may be used constantly for months without any blockage occurring. In view of the above difficulty, I have devised a similar pipette with a larger bore and graduated to ¼ c.mm. This latter can be easily penetrated by a fine wire and cleaned in case of a stoppage. Such a pipette (of the larger bore) may be preferred by beginners, but for quicker work and for those who have had some practice the ⅛ c.mm. pipette is the better. To enumerate leucocytes or parasites, suck blood into the pipette and expel ⅛ c.mm. on to a glass slide. Breathe on the slide to keep blood moist, and spread the latter with pricking needle into a small square about 4 × 4 mm. Stain this small ⅛ c.mm. blood film in the usual way. To estimate the number of required objects in this film, one must have a mechanical sliding stage and a square diaphragm in the eye-piece. All the leucocytes or parasites in the film may be counted, or the number may be calculated from the numbers found in two or three sample bands taken across the square film.

Fuller instructions for use are supplied with the pipette, which is manufactured by C. Baker, 244, High Holborn, London, W.C.

DAVID THOMSON, M.B., Ch.B. Edin., D.P.H. Camb.
Liverpool.

CHARING CROSS HOSPITAL MEDICAL SOCIETY.—A kinematograph display of bacterial processes will be given in the Out-patient Hall of Charing Cross Hospital on Tuesday, Feb. 27th, at 5 P.M., to which all students and medical men are invited. Members of the profession who desire to be present should communicate with the honorary secretary, Mr. Kenneth V. Smith.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 17, 1912.

Lord Lister.

FULL of years and honours, the greatest Englishman of the nineteenth century has gone to his rest. We claim this position for Lord LISTER, not only by reason of his actual achievements in the preservation of life and in the relief of suffering, but still more by reason of the qualities of intellect and of character which rendered those achievements possible; qualities among which an absolute devotion to the ascertainment of truth was perhaps the most conspicuous. To him, as to the few philosophers of approximately equal rank who have preceded him, an established truth was a possession too inestimable to be measured by ordinary standards of value; and no pains, no self-sacrifice, could be too great to be spent in its attainment. He had the signal advantage, as regards contemporary fame, over the only men who could be mentioned as his intellectual peers, over NEWTON, over THOMAS YOUNG, over DARWIN, that the problems to which he addressed himself were of direct and immediate bearing upon the welfare of the human race, and that his solution of them placed him at once in the forefront of human benefactors. Those problems, and especially the central one among them, the cause of decay and putrefaction in wounds, and the reasons why these changes were more prone to occur when wounded persons were collected together within a limited space, had occupied the minds of many keen observers at many times and in many countries; and WILLIAM CLOWES, the great English surgeon of the sixteenth century, has left behind him not only a description of the conditions which could scarcely be surpassed, but also a lucid statement of the reasons which forbade him to accept the belief that they were due to the use of poisoned bullets or weapons by the Spanish soldiery against whom his countrymen were contending in the Netherlands. In those days the circumstances conducive to widely spread gangrene hardly existed except in time of war, and, save for a few so-called "hospital" cases, it was not until the beneficent action of anæsthetics began to bring great numbers of peaceful people under the hands of the surgeon that there arose a pressing danger of the practical neutralisation of the expected good by the occurrence of great and wholly unexpected evils. Even in private houses, and, as it seemed, amid surroundings of the most favourable kind, the operations which, because they could be rendered painless, were freely and hopefully undertaken, were in a lamentable proportion of cases rendered of no account by death; while the surgical wards of many hospitals became veritable pest-houses, from which escape with life could hardly be regarded as probable. It seems scarcely credible to-day, but is none the less true, that only half a century ago it was gravely proposed that surgical hospitals should be temporary buildings, which should be destroyed by fire, as dangerous nuisances, after the fulfilment of two or three years of existence, or as soon as gangrene became of common occurrence among their inmates.

At this time LISTER, who was the son of a scientific father, and had been trained in a scientific direction by his influence and his example, had already for some years been engaged in careful research, exercising and developing the faculties essential to accurate investigation. He had learnt how to frame and how to verify or to refute hypotheses; he had learnt how to establish facts in such a manner as to render each one a stepping-stone to further progress; he had learnt to question the accuracy of his own conclusions, and this the more stringently, the more they seemed to be conducting him towards some wished-for goal. He was at the zenith of his powers, gazing sadly at the evils of unknown source and origin by which the best skill of the surgeon was so constantly defeated, when the news came to him of PASTEUR'S discovery of the cause of putrefaction, and he hastened to acquaint himself with details which he at once perceived, with the intuition of genius, might supply him with the clue of which he was in search. Each of the two great men has vied with the other in extolling the share taken by his fellow in the production of the total result; and it is manifest that there can be no question of originality between them. It is unlikely, to say the least, that the attention of PASTEUR himself would ever have been directed towards hospital phenomena, and the range and scope of those phenomena were sufficiently wide to furnish complete occupation for many years of strenuous and persevering industry. We have sometimes been reminded, by the history, of what has been recorded by COLERIDGE concerning the origin of penny postage. A pedestrian, wandering in Cumberland in the early "thirties" of the last century, found a poor girl crying in the road because she was unable to pay the postage of a letter from her brother, who had gone south in search of work. The pedestrian paid the postage, and gave the girl her letter. Most tourists, in similar circumstances, would probably have done the same; but this tourist was ROWLAND HILL, and the incident germinated and bore fruit. Most surgeons would have been interested in PASTEUR'S discovery; but the only one who saw its full significance was LISTER, and his life was thenceforward devoted to the realisation of the vision which had been revealed to the insight of his genius, but which never could have been realised without the most patient, continuous, and unwearied industry. The generation is passing away which witnessed the labours of the great discoverer in the direction of perfecting his work; but none of those who now profit by it should forget the opposition which it encountered or the placid courage with which successive positions were either justified and maintained or were abandoned as soon as their originator became convinced of their unnecessary character. Gradually, and step by step, the conditions essential to the asepticity of wounds and injuries were established; and the great philosopher was revealed to the world in the full lustre of his fame.

The picture is worth gazing upon. For the details of

Lord LISTER'S career, the opposition which his discoveries encountered, and the completeness with which this opposition was overcome, we refer our readers to the notice of his life which occupies other portions of our columns. But those who know or who study these details will recognise that even his luminous intellect would have failed to impress itself upon his generation had it not been allied with other qualities only less great, and, unfortunately, not too common. The brilliant imagination, the almost inspired genius, the philosophic insight, would have been of comparatively small account without the support which they derived from unflinching courage and untiring industry. Without these aids, the sneers and contumely with which his earlier announcements were received could scarcely have failed profoundly to discourage him, or even to interrupt the course of his investigations; but he passed through the turmoil as if hardly aware of its existence, and confined himself from first to last to the facts and questions which were of essential bearing upon the truths which it was his mission to establish. Perhaps few things were more galling to his early adversaries than the manner in which he refrained from "railing accusation," and, while never omitting to deal with any real difficulty, treated difficulties which were imaginary or irrelevant with an indifference that must sometimes have been more galling than expressed contempt. Eager to teach and to explain, he was always accessible to those who sought with sincerity for enlightenment, and the stores of his knowledge and of his experience were at the command of the humblest of those who asked for them. It was his privilege to complete the great work which he began, to build up from the foundation a system of asepticism which leaves nothing to be desired by those who have mastered the principles on which it rests, which has opened all the great cavities of the body to the healing hand of the surgeon, which has removed the pains or preserved the lives of countless thousands of sufferers in every portion of the globe, and which has raised English surgery to a pinnacle from which not even the presumptuous ignorance of politicians will be able to take it down. Our country has given to the world and to the profession the record of a stainless life, of an intellect at once brilliant and profound, of an industry which never wearied, of a courage which never failed; and these qualities, sufficient to constitute greatness in any department of human activity, were so combined in LISTER as to justify our opening claim on his behalf. He was unquestionably the greatest Englishman of his century.

The National Insurance Act.

THE inconvenience, indeed, in some circumstances, the terrible mischief, that accompanies our system of party politics has been remarkably shown during the last two or three months in the attitude of the press towards the resolutely expressed intention of the medical profession to obtain fair treatment under the Insurance Act, treatment which should recognise the high as well as onerous nature of our duties and the costly and elaborate training which those who enter the medical profession have to undergo before they are qualified by law to discharge those duties. The Chancellor of the Exchequer, in a measure the good intentions and actual beneficence of which have been freely acknowledged, proposes to deal with the medical profession on lines which no doubt seem to him wise, but without taking into consideration any of the higher associations of our calling, and, most extraordinary omission of all, without consulting either the educational bodies responsible for the maintenance in this country of a supply of properly educated medical man, or the General Medical Council, itself a Standing Committee of the Privy Council, formed to be a guarantee to the public that the medical service of the country should be adequate and duly progressive. Neither our educational nor our disciplinary authorities were asked to assist in the construction of the measure, yet their unwillingness to discuss details at a moment's notice and in oddly assorted company has been stigmatised by Mr. LLOYD GEORGE in violent terms.

If the Government desire the help of the great corporations—as they should—to assist them in the present situation, delay in the working of the Act, it seems to us, must be granted. The medical profession object to having their professional lives turned upside down, and the fact that in certain directions the process might work for their own good has not reconciled the general practitioner to the upheaval. He sees the undoubted ills. Again, the Act contains in it many things ominous to the progress of medical science and to the maintenance of those great charities which are alike the glory of our professional life and the mainstay of our professional education. But the remarkable display of opposition by the medical profession to the National Insurance Act has been attributed mainly to political feeling; and exactly the same is said of those who are willing to work the Act. Whatever reservations the latter make they are said to be influenced by their Liberalism, while those who consider that reasonable delay should be granted before the medical provisions come into working are regarded as enemies to the existing dispensation. This is particularly unfortunate, because an Act to insure the nation against the consequences of invalidity should offer a remarkable opportunity for the medical profession and the public to enter upon relations of mutual trust; under its working they should come to understand each other better. As a matter of fact, owing to the endeavour to hall-mark certain sections of the medical profession as Socialists and certain sections as Tories, all the professional issues have been confused, and a great chance of reasonable coöperation between medicine and the public may have been lost for a generation.

We understand that the Royal College of Physicians of London and the Royal College of Surgeons of England have now constituted a joint committee, in association with which we hope the Society of Apothecaries of London will be found. The committee will consider the situation in regard to their high responsibilities as representing the bodies from which the vast majority of English medical practitioners receive the qualifications under which they

practise, whatever other academic distinctions they may acquire, and as therefore being virtually in charge of medical education in this country. Their course must then be influenced by the result of the meeting of Representatives of the British Medical Association to be held next week. If the Act can be made workable it will call for exceeding great faith from the medical profession, who will have to enter upon engagements of a strict and onerous sort with no definite guarantee of adequate return. That the Insurance Commissioners will be able to make the appointments under the Act desirable ones may be true, and perhaps some system of collective bargaining may enable practitioners to obtain fair play in many localities. But all this is nebulous, and to us it seems that there is nothing but ordinary caution in asking for a term of delay in which many of the difficulties might be cleared up and the uncertainties removed.

Annotations.

"Ne quid nimis."

THE INTERNATIONAL OPIUM CONVENTION.

THE International Opium Convention, which was signed at the Hague on Jan. 23rd by the representatives of twelve Powers, is an instrument designed for the suppression of the abuse of opium, morphine, cocaine, and other drugs which give rise to analogous abuses. The parties to the Convention are Germany, the United States of America, China, France, Great Britain and Ireland, Italy, Japan, the Netherlands, Persia, Portugal, Russia, and Siam; but the Netherlands Government is empowered to invite all the Powers of Europe and America not represented at the International Conference to designate a delegate armed with the full powers necessary for the signing of the Convention. It is important to note that among the Powers which were not represented at the Hague Conference were Turkey, Peru, Bolivia, and Switzerland. The bulk of the raw material from which morphine is extracted is Turkish opium; coca leaves and crude cocaine are chiefly produced in Peru and Bolivia, and Switzerland is growing in importance as a producer of fine chemicals, of which some have the same injurious effects as the alkaloids of opium and coca leaves. Without the coöperation of these Powers, which possess natural or industrial advantages for the production of narcotic drugs, the effective suppression of the illegitimate traffic in opium, morphine, cocaine, and the like would hardly be possible. It is therefore hoped that the four Powers named will be induced to come into line with the twelve signatories. The Convention virtually binds those Powers which ratify it respectively to enact legislation to give effect to the principles embodied in the agreement. As to raw opium, the contracting Powers agree to enact laws to control its production and distribution, to limit the number of ports through which its importation or exportation shall be permitted, and to prevent its exportation to countries which prohibit its entry and control its exportation to countries which limit its importation. As to prepared opium, the Convention aims at the suppression of the manufacture, distribution, and use of opium made into the form of an extract suitable for consumption. Up to this point the desired objects can be obtained, so far as this country is concerned, without any undue interference with existing trade interests, although the right to import raw opium for legitimate manufacturing purposes will be restricted to duly authorised persons. The articles of the Convention relating to medicinal opium, morphine, cocaine, and heroin bind the ratifying Powers to enact laws which must necessarily infringe on an industry which is in a particularly flourishing condition in Germany, England, Scotland, and Switzerland. A considerable proportion of the output of the narcotic alkaloids manufactured in these countries supplies a demand which is neither medical nor legitimate, in spite of the fact that the manufacturers may be ignorant of the ultimate destination of their products. Large quantities of morphine, for instance, are smuggled into China, and it is known that in the year when the duty on that alkaloid imported into the Celestial Empire was increased from 5 to 200 per cent., *ad valorem*, the quantity imported fell from four tons to a few ounces, although, it is said, the consumption increased. Similarly, the occasional seizures of heavy consignments of cocaine by the Indian Customs authorities indicate the existence of a not inconsiderable illicit traffic in that drug in India alone. When the sale of morphine and cocaine is restricted to proper uses only there will necessarily be a large decrease in the quantities manufactured. The Convention requires the contracting Powers to enact such pharmacy laws and regulations "to limit the manufacture, sale, and use of morphine, cocaine, and their respective salts to medical and legitimate uses only" in the following manner—by issuing licences to manufacturers of, and dealers in, these products in respect of their places of business, and by requiring them to register on their books the quantities manufactured, imported, exported, or sold. Such regulations are also to apply to medicinal opium; to all preparations (official and non-official, including the so-called anti-opium remedies) containing more than 0·2 per cent. of morphine or more than 0·1 per cent. of cocaine; to heroin, its salts and preparations containing more than 0·1 per cent. of heroin; and to every new derivative of morphine, cocaine, or their respective salts, or to any other alkaloid of opium which might, after generally recognised scientific investigations, give rise to similar abuse and to result in similar injurious effects. In framing the proposed measures of legislation the contracting Powers are not required to apply the regulation in regard to the recording of sales of morphine and cocaine in the case of prescriptions of medical practitioners, or in the case of sales by pharmacists in the ordinary course of business. As a matter of fact, the law of this and most of the other countries concerned already makes provision for transactions of this kind, but apart from the obligations of Great Britain, as a party to the Convention, it would be in keeping with the spirit of the proposals if the British Government, in framing the measure which will be necessary to give effect to the international agreement, were to take the opportunity to increase the stringency of the conditions under which the drugs in question may be distributed. If some legal limit were placed on the number of times a prescription for a compound containing morphine or cocaine could be dispensed, pharmacists would be happily relieved of the necessity of depending entirely upon their own judgment. The last day of this year is the date by which it is hoped that the Government of the Netherlands will have received ratifications from the Powers, after which it is expected that the necessary measures of legislation will be framed without much delay.

IN MEMORY OF THE LATE DR. BOURNEVILLE.

A COMMITTEE has been formed, under the immediate presidency of M. Pierrotet, Mayor of the Fifth Arrondissement of Paris, with M. Mesnard, of the Asile de Bicêtre, as secretary, for the purpose of honouring the memory of the late Dr. Bourneville, the founder and editor of the *Progrès Médical*. It is proposed to raise a monument over his grave at the Père Lachaise cemetery, and another at the Bicêtre

Hospital with which he was connected for so many years. In this manner the great services he rendered may be recalled and serve as an example to others. Dr. Bourneville will be best known to our readers, perhaps, for his intimate association with the earliest movements to introduce the technical training of hospital nurses. He was inspired by a profound admiration for Miss Florence Nightingale and anxious that his country should benefit by her teaching. As a Member of Parliament as well as of the Paris Municipal Council, he largely contributed to the secularisation of the French hospitals, and the consequent introduction of competent trained nurses. He likewise helped forward various movements in favour of special maternity hospitals. As further examples of his deep interest in social problems may be mentioned his advocacy of cremation and of more systematic medical and institutional treatment of the feeble-minded, while as a member of the Superior Council of Hygiene he worked for sanitary reform by promoting the water-carriage system of sewage. He assisted Professor Charcot to edit the *Archives of Neurology*. The secretary of the Society for the Support of Cremation, M. G. Salomon, 112 bis, Boulevard Malesherbes, Paris, is the treasurer of the memorial committee. Among the members of this committee we notice the names of Dr. Augagneur, who is one of the Ministers in the newly formed Government under M. Poincaré; Dr. Marcel Baudoin, Syndic of the Association of the French Medical Press; Dr. Paul Brousse, recently president of the Paris Municipal Council; Dr. Beurmann, president of the Hospital Society; Dr. Maurice Letulle, president of the Anatomical Society; Dr. Paul Sérieux, president of the Medico-Psychological Society; Dr. Thoinot, president of the Society of Hygiene; Dr. Demelin, Dr. Navarre, Dr. Jules Voisin, and Dr. Landouzy, dean of the Paris Faculty of Medicine. M. Léon Bourgeois, who was formerly Prime Minister, is associated on the committee with two other celebrated Prime Ministers, M. Clemenceau and M. Combes, and with M. Mesureur, director of the Assistance Publique. The executive also includes Professor Barrier, director of the Veterinary School at Alfort, and Dr. Bonnaire, the well-known obstetrician, and the general secretaries are Dr. Paul Cornet, Dr. Julien Noir, and M. Pujol, the architect. Considering the great esteem in which the late Dr. Bourneville was held and the influential support thus accorded to the movement, there should be no difficulty in suitably commemorating his life work.

THE HOUSING QUESTION IN VANCOUVER.

A FREQUENT correspondent writes from Vancouver the following description of how the question of overcrowding is affecting the accommodation of the labouring classes in Vancouver:—"Public health problems are to the fore everywhere, and overcrowding amongst labourers is a serious concern in the city of Vancouver. It has been extending at a great rate, but the population has more than overtaken the accommodation, particularly as railway extensions have cleared away large blocks of huts, or, as they are termed in Western Canada, 'shacks,' which formerly sheltered a myriad of the poorest people. I have been taken through many houses which take the place of common lodging-houses, and other lodgings. The lowest price for a bed in a dormitory is 20 cents. I should estimate that each lodger has twice the cubic space he would get for 3*d*. in an English common lodging-house, he has a better bed and bedding, his room is better ventilated, and he has a water-closet and washing-place on the same floor. Probably at night extra men will be found sleeping on the floor, or on mattresses laid on the floor, and it is practically impossible at present to prevent this, for there is not in the town accommodation for housing the winter population. It is hoped that next year the demand may be overtaken, but the conditions are almost too difficult to be met. Throughout Central North America there is great need for labour during the summer, when the prairies are consequently drawing men to them. These men have no work to do in the winter and, dreading the severity of the climate, they migrate to the Pacific Slope; consequently the towns from Vancouver to Los Angeles have to house in winter an enormously increased population, a population of white men be it observed. The Chinese have different conditions, for the Chinese on the prairies are cooks or laundrymen, and their occupation is permanent. The extra Chinese in the towns in winter are men who work in the salmon canneries on the Pacific Slope. Many 20 cent beds have been provided on a semi-charitable basis—like that of the Rowton Houses in London and the Bevington House in Liverpool—in the Mission building, so far partly completed and lodging 250 men, where there are a mission room, large dormitories, good lavatories, a laundry, and a baggage room. Here the city accommodates some men of good character but without funds at the time. Above the 20 cent line are houses with better beds and choicer company for 25 cents in large dormitories and 50 cents (2*s*.) in cubicles, and lodgings at 50 cents (2*s*.) and 75 cents (3*s*.) a night in separate rooms. These are all carefully inspected by the Health Department; their sanitary arrangements and ventilation are very good, and fire protection is provided by swing doors and fire escapes. The problem of housing the Chinese is more difficult, but it is hoped that this will soon be solved by the development of a Chinese settlement now under construction to replace the old village which was swept away in the preparations for the new railway." The difficulties which confront a new community, when growing so rapidly as the modern Canadian towns grow, must be enormous. Though the sanitary conditions of the day are faced and provided for, the pressure is maintained by the influx of population. Larger sewers and an increased water-supply are needed almost before the ones immediately required are completed, and in spite of an anxious and wakeful Government overcrowding has come into existence in many places, and must continue to be steadily faced.

BLUE ATROPHY OF THE SKIN FOLLOWING COCAINE INJECTIONS.

Dr. William S. Gottheil, of New York, has contributed to the *Journal of Cutaneous Diseases* for January, 1912, a description of changes in the skin following habitual hypodermic injections of cocaine and morphine in a woman aged 31, an ill-nourished subject, who had been administering the drugs to herself for about seven years. The actual cause of her going to Dr. Gottheil for treatment was a multiple infection of the thighs, buttocks, and arms with pyogenic cocci, introduced in all probability by a dirty hypodermic needle; this infection was of three weeks' duration only, and she had never had a previous misadventure of the same kind. There were, however, a great many atrophic pigmented areas of skin scattered about over the thighs, buttocks, and arms. These were more or less rounded in shape, and were on an average equal in size to a large pea; each was a sharply limited depression in the skin, and had a blue tint varying in intensity from a deep blue-black to brighter shades, causing them to contrast vividly with the anæmic pallor of the surrounding skin. The patient was quite sure that each of these patches represented the site of an injection of cocaine; she was positive that introduction of morphine alone beneath the skin had no such effect. The development of these areas caused her no concern, so that presumably there was no inflammatory process responsible for their production. She bought her drugs in clear solution and used the ordinary type of hypodermic needle. A histological examination of

the areas showed that the pigment, which was very black, occurred in rounded or irregular granules, massed together in some spots. It was scattered throughout the cutis, but lay principally in its central portion; some of it was definitely within lymphatics, and in many places the granules were surrounded by an inflammatory exudation of cells. The atrophic process involved the entire cutis. Unfortunately the quantity of pigment was so small that it could not be tested chemically. Dr. Gottheil states that he has never seen any such lesions following subcutaneous injection of drugs, though spots of blue pigmentation without atrophy are not uncommon as a result of hypodermic introduction of various drugs. There are only two other cases on record, so far as he was able to ascertain, in which the same combination of pigmentation with atrophy has occurred as a result of injection of drugs; in one of these the offending substance was morphine, in the other cocaine. Dr. Gottheil's patient said that she had seen similar spots in other victims of cocainism. The nature of the pigmentation is doubtful; possibly the granules are steel particles, but this fails to explain the rarity of the lesion and the concomitant atrophy.

THE LOGIC OF FADDISM.

THAT some people eat too little and that others eat too much; that most people occasionally, and some habitually, eat unsuitable food, or eat suitable food in an improper manner or under improper circumstances; that food that is suitable for one person may be quite unsuitable for another person, or even for the same person at another time and under other conditions; and that from these deviations from normal conduct arise many of the ills that flesh is heir to—these, surely, are truisms. And from concentration of attention on truisms without due regard to perspective most fads take their birth. Mr. Upton Sinclair, who focussed public attention with regard to the Chicago stock-yards in the direction previously indicated in these columns by our Special Sanitary Commissioner, has views on fasting[1] as a cure for nearly every ill, and his opinions have received wide publication in lay magazines and in the daily press. They have lately appeared in book form. Suffice it to say that he advocates in many circumstances abstinence from food of all kinds for a period lasting until the return of hunger—which, according to him, within a day or two of beginning the fast, disappears and remains in abeyance for a varying period of time. In response to a circular of inquiry sent out by Mr. Sinclair as to the results in those known to have followed his method, he received reports of benefit in 27 cases of indigestion, 14 of constipation, and in smaller numbers of colds, tuberculosis, poor circulation, headaches, anæmia, scrofula, bronchial trouble, syphilis, liver trouble, general debility, chills and fever, blood poisoning, ulcerated leg, neurasthenia, locomotor ataxia, sciatica, asthma, excess of uric acid, epilepsy, pleurisy, impaction of bowels, eczema, catarrh, appendicitis, valvular disease of heart, insomnia, gas poisoning, grippe, and cancer. We are by this time quite prepared for the familiar phrase that follows: "45 of the cases having been diagnosed by physicians." We have some curiosity to know how it happened that "out of the 109 persons who wrote" [in reply to Mr. Sinclair's questions] "100 reported benefit and 17 no benefit" (p. 103), and suggest that statements of this kind, even if capable of some explanation not clear to the ordinary reader, may have led to the neglect by responsible journals to take his work seriously—a conspiracy of silence in which Mr. Upton accuses THE LANCET and the *New York Times* to participate. Mr. Sinclair, believing the meat which he had hitherto been taking to have been the cause of his headaches, dyspeptic and other symptoms, gave up eating meat. The troubles disappeared and he became forthwith a vegetarian on principle as well as in practice. But, alas! in about three years the same troubles reappeared, notwithstanding his strict adherence to a "raw food dietary." Then he read somebody's book, with the result that he returned to the use of meat, and presto! his troubles disappeared again. He has apparently since stuck to the use of meat, which he found suited him better than vegetarian food—though the same indispositions the cure of which he now attributes to meat food had previously disappeared on his taking to vegetarianism; and he expresses the opinion that, so far as he is concerned, beef-steak is the most easily digested and most easily assimilated of foods (p. 168). The fact is, that in a lack of general applicability lie the uselessness and danger of all faddist methods, while Mr. Sinclair errs beyond that point, in that he lays down as principles things that are clearly unsound. For instance, he asserts: "That anyone could die of lack of food without feeling a desire for food, is absurd on the face of it." Again, discussing alleged deaths under the fasting cure, he says that "people might die very frequently" [under the treatment] "without that being any argument against the cure." That would depend upon whether the relation of cause and effect were established. He and thinkers of his calibre fail to see that the converse proposition is equally true—viz., that people may get better under any kind of "cure" without that being any argument for the cure. The multiplication by the food faddist of plans to avoid dyspepsia is for the most part an imitation of the policy of the householder who, hearing of a patent stove that was warranted to save half his coal, bought two stoves that he might save all of it.

MALIGNANT CHORDOMA, INVOLVING BRAIN AND SPINAL CORD.

IN the *Journal of Nervous and Mental Disease* for January of this year is a paper of considerable pathological interest by Dr. Smith Ely Jelliffe and Dr. John H. Larkin, of New York. It records the occurrence of a tumour of great rarity—viz., chordoma, a malignant cartilaginous growth of notochordal origin, invading the base of the skull and brain, with multiple metastases in the spinal cord and column. The present case is the seventh recorded in the literature. The patient was a young married woman of 36, with a clean bill of health up to the onset of the illness to be described, who suddenly developed a sixth nerve palsy on the left side. Severe headache followed, with neuralgic pains in the distribution of the left trigeminal nerve, extending sometimes to the back of the head. Not long after, persistent vomiting set in and the patient began to lose flesh rapidly. Some months after the commencement of the affection it was found that the right eye was completely blind, while vision was very defective in the left. The pupils were widely dilated and inactive to every form of stimulus. There was total external ophthalmoplegia as well, the eyes being immobile in the central position. On the left side considerable ptosis was noticed. Facial movements were good, and audition was normal. The limbs were somewhat wasted and muscular power was diminished, but no sensory changes could be detected. Both ankle- and knee-jerks were absent, and there was a slight degree of Rombergism. Within a comparatively short time, however, the symptoms became much more severe. Gradually increasing somnolence set in, with mental confusion and dreamy delirium; further cranial nerve involvement, in the shape of a left facial palsy, indicated a spread of the basal tumour, the condition having been so diagnosed. Then followed a motor and sensory palsy of the left fifth nerve, a left hemiplegia and hemianæsthesia, and a progressive

paraplegia, with total loss of motor, sensory, and sphincter functions. Hallucinations of sight, hearing, and smell ensued. Finally, came a sanguineous discharge from the right nostril, and after eight months of acute suffering the patient died from profound inanition. At the necropsy the brain was found to be held down in the base of the skull by a huge tumour mass, through which ran the first, second, third, fourth, fifth, and sixth cranial nerves, while others were flattened or distorted by intracranial pressure. The dimensions of the growth were 11 × 6 × 7 cm. The base of the skull was extensively necrosed by tumour invasion. Both orbital plates of the frontal bone, the crista galli and cribriform plate of the ethmoid, the body and lesser wing of the sphenoid, were all destroyed. The pituitary body could not be found. Tumour growth had spread into the nares, the sphenoidal sinuses, and even into the antrum of Highmore. At first the growth was supposed to be a sarcoma, but microscopical examination showed that the matrix of the tumour was like cartilage in some places and like mucous tissue in others. There were rows of cells in a homogeneous groundwork which contained many open spheroidal spaces, due no doubt to the coalescence of cells. The spaces were sometimes sufficiently extensive to be described as cysts. The cells were relatively large, with deeply staining nucleus and many vacuoles in the protoplasm. The matrix was in many places hyaline-looking, staining light blue with hæmatoxylin. Very few blood-vessels were found in the tumour, which in its more developed parts was identical with the tissue of the notochord. The paper of Dr. Jelliffe and Dr. Larkin contains an abstract of all the previously recorded cases.

DUTCH DROPS.

A CORRESPONDENT has forwarded us a sample of "a quaint remedy for urinary disorders called 'Dutch drops,'" which appears to have vogue chiefly amongst seafaring people, its efficacy as a diuretic amounting in their minds to a conviction. "Dutch drops" are referred to in certain homely books on medicine as a residuum obtained by the rectification of turpentine or by distilling resin, but it is admitted that the original Haarlem formula is much imitated. Various formulæ are given, including the compounding of oil of turpentine, guaiacum, amber oil and cloves, balsam of sulphur, linseed oil, ammonia, and so forth. It is stated to be "detergent, diuretic, stimulant, and vulnerary." Amongst the synonyms of Dutch drops are: guttæ Hollandicæ, empyreumaticum Batavicum, ol. Haarlemensis, and Tilly's drops. The sample submitted to us appears to be the genuine Haarlem oil, which, according to its wrapper was invented as far back as 1696 by one Tilly. "This medicine," we are told, "works miracles with every one, that makes use of it, and the Grace of the Omnipotent God is experienced in it to admiration. When you take this remedy it unites itself to the Stomach, and is the same as a flying Mercury not letting the vapours rise without being mixed with them; it likewise prevents at moist humours from running through the Veins or Nerves, accompanying them until they pass through the pores. Thus it communicates itself and leaves its virtue notwithstanding afterwards it may be expelled by urine or stool." In similarly quaint terms the wrapper also declares this "medicamentum gratia probatum" to be a cure for bad-smelling urine, gravelly stone, all kinds of fevers and distempers, French disease, worms, palpitations, megrim, ulcers, cancers, disorders of the eyes and ears, colic, lying-in inconveniences, fits, and so on. The sample we received was a dark brown oil smelling strongly of turpentine. It did not contain guaiacum or ammonia. There was sulphur present in combination with the oil, for on oxidising the oil with nitric acid some sulphuric acid was produced. Further, on heating the oil with alkali and a few drops of lead acetate solution there was a distinct blackening. A slip of lead foil similarly turned sheeny black when heated in the oil made alkaline with caustic soda. The oil was completely soluble in ether. That it did not consist exclusively of turpentine and its derivatives was evident from the fact that a soap was formed when it was boiled with an alcoholic solution of caustic soda. The soap so obtained when decomposed with a mineral acid yielded fatty acids resembling linoleic acids. It seems probable, therefore, that the specimen was a true specimen of the original Dutch drops made by boiling sulphur with linseed oil or turpentine or both. The medicament clearly aims at presenting sulphur in organic combination, and preferably an oily one, resembling in this respect relatively modern pharmacological products as the ichthyols. Such attempts at presenting sulphur in the organic shape with the aid of fats and volatile oils, are interesting in view of the therapeutic success attending the use of, say, arsenic and mercury in complex organic molecules.

IMPROVEMENT IN SPONDYLITIS DEFORMANS UNDER FIBROLYSIN.

AT a meeting of the Société Médicale des Hôpitaux of Paris on Dec. 1st, 1911, M. E. Rist described a case of remarkable improvement in spondylitis deformans, with involvement of the shoulder and hip-joints (*spondylose rhizomélique*), under treatment by fibrolysin. Some years previously he reported a similar result in which after an attack of gonorrhœa the spine had been ankylosed for 14 years. The patient became an invalid unable to do any work. Under the treatment he so much improved that he could almost gain a living. In the present case the patient was a Polish hatter, aged 23 years. He was admitted into the Laennec Hospital for cough, dyspnœa, and pains in the limbs on June 24th, 1911. In January and again in March hæmoptysis occurred. In May rheumatic pains began in the lower limbs and then affected the upper. On admission he was emaciated, weighing 47½ kilogrammes. The temperature ranged from 99·5° to 100·4° F., and the respirations were 28. At the apices of the lung the respiratory murmur was weak, and in the right supraspinous fossa dry crackling sounds were heard. He coughed frequently, but expectorated little. The most striking symptom was rigidity of the neck with limitation of movements. Flexion was almost impossible and extension was only a little more free. Limitation of rotation and lateral flexion was equally marked. All these movements were painful. On endeavouring to increase them passively invincible resistance was encountered and acute pain was produced. The whole of the cervical and dorsal spine was painful and ankylosed. There was marked cervico-dorsal kyphosis, contrasting with lumbar lordosis. The left shoulder-joint was painful, and its movements were limited and accompanied by crackling; the left hand could not be placed on the head. The right shoulder was less painful, and its movements were not limited. There were also pains in the hip-joints, but they had been more severe before admission. The obliquity of the ribs was marked and respiration was entirely diaphragmatic. The case was thus a typical example of the *spondylose rhizomélique* of Marie. So was its etiology. A year before admission the patient contracted gonorrhœa and a "morning drop" (*goutte matinale*) still persisted, in which gonococci were found. The urethritis was treated by M. Legueu, and at the time of the report had disappeared. For the vertebral ankylosis M. Rist gave from July 22nd to Nov. 3rd 24 subcutaneous injections of 2 cubic centimetres of a solution containing 20 centigrammes of fibrolysin to the cubic centimetre. On July 28th, after 1·2 gramme

of fibrolysin had been injected, movements of the head and shoulders were easier and more extensive. At the end of October the movements were almost normal. Nevertheless, some rigidity of the spine persisted, and the kyphosis and lordosis were still perceptible. Movements of the left shoulder-joint did not become quite normal. The upper ribs did not regain all their mobility, and the diaphragmatic type of respiration persisted. The pains completely disappeared, the patient gained 5 kilogrammes in weight, and resumed work. M. Rist does not doubt that if he had been able to combine gymnastics and massage with the administration of fibrolysin he would have obtained a still better result. The success of fibrolysin in such cases is not in accord with the pathological theory that spondylitis is primarily due to softening of the bones (rarefying osteopathy), and that ossification of ligaments follows as a compensation for the insufficient solidity of the skeleton. M. Rist suggests that there is at first hyperplasia of the peri-articular fibrous tissues, as otherwise it is impossible to explain the action of fibrolysin. It is noteworthy that the spondylitis had not lasted more than two months when the treatment was begun. With regard to the pulmonary tuberculosis, it at first seemed more serious than it was, because some of the symptoms which were supposed to be due to it were the result of immobility of the thorax from costo-vertebral arthritis. Expansion of the apices of the lung was therefore almost completely suppressed, the respiratory murmur was diminished, and dyspnœa was increased. It is also noteworthy that the fibrolysin had no injurious effect on the pulmonary tuberculosis. The view has been put forward that the drug would interfere with cicatrisation of tuberculous lesions.

THE EFFECTS OF STRENUOUS ATHLETICS IN THE AMERICAN NAVY.

IN the *Journal of the American Medical Association* of Jan. 6th is reviewed an important pronouncement contained in the report of the Surgeon-General of the American navy on the effects of competitive athletics in the training schools and colleges. With an unparalleled opportunity for observing during their school course and in their subsequent careers large classes of young men, the Bureau of Medicne and Surgery of the Amercan Navy has come to the conclusion that spectacular and competitive athletics are undesirable. It is held that the prolonged and rigorous course of exercises necessary to excel in physical sports is injurious in its after-effects. Under the conditions of service at sea it is impossible to continue rigorous exercises; the athlete falls a prey to degenerative changes, tends to become obese and to lose physical stamina, and fails to render as many years of efficient service as does his less athletic classmate. The records of 625 athletes of the Naval Academy classes from 1891 to 1911 were examined to determine the bearing of early athletics on physical efficiency in after life. Of these, 21 died—6 from tuberculosis, 8 from mental and nervous disease, 2 from alcoholism indirectly, 1 from acute dilatation of the heart, and 1 from valvular disease of the heart. The last two deaths were directly attributed to running. One death was due to an injury received during football. Of the remaining 604 athletes in the service, 198 have had disabilities noticed in the official records to which athletics stand in a possible or probable causal relation. These disabilities have not necessitated discharge, but have caused impaired service. Of these 198 men, 48 had abnormal conditions referable to the heart and blood-vessels, such as arterio-sclerosis, organic cardiac disease, murmurs, irregular and rapid cardiac action and hypertrophy, and dilatation of the heart. In 16 the joints or motor apparatus were involved; in 11 the kidneys; in 17 there was patent tuberculosis or tuberculosis was suspected; in 16 there was neurasthenia associated with gastric complications. There were 25 cases of appendicitis and 15 of hernia, both of which conditions appeared to be associated particularly with a football record. The opinion is expressed that long distance racing is productive of serious harm. This severe arraignment of competitive athletics has been corroborated in civil life by experiences in schools and universities. The Bureau of Medicine and Surgery of the American Navy does not recommend that athletics in the navy should be entirely abandoned, but is of opinion that in their strenuous competitive form they are dangerous. Moderate athletics are encouraged, and in the Naval Academy the Swedish system of exercises is now being tried with satisfactory results.

ADMINISTRATION OF THE PHARMACY ACTS.

DURING the last few years the duty of administering the penal clauses of the Pharmacy Acts, which belongs to the Pharmaceutical Society, has entailed a much greater amount of work than was the case before the enforcement of the Poisons and Pharmacy Act, 1908, by which enactment a new class of poison sellers—namely, a class licensed to sell arsenical sheep dips, weed-killers, and the like—was created. In the year before that Act came into force the society's law department investigated 453 cases of alleged infringement of the Acts, but in the year following the enforcement of the 1908 Act four times the number of cases of alleged infringement were examined. The main cause of this increased activity was that the new class of licensed poison sellers, which consisted chiefly of seedsmen, florists, and ironmongers, had not been trained to understand the necessity of a precise observance of the precautions which the law requires to be taken when potent compounds are sold by retail. In chemists' shops the "poison book" has been used every day for the last 40 years or so, but an ironmonger had not been accustomed to take any precautionary measures of the kind when dealing with his customers, for the reason that it had been illegal for him to sell compounds of arsenic and nicotine. When the ironmonger obtained his poison licence he was apt to forget the conditions of sale with which he was required to comply, and hence the large increase in the number of cases of irregular sales of poisons which the Pharmaceutical Society was called upon to investigate. That the unqualified poison sellers are now acting with greater care seems to be indicated by the fact that last year the number of cases of alleged infringement of the Pharmacy Acts which were made the subject of inquiry was considerably less than in the previous year. Thus, according to the annual report of the registrar of the Pharmaceutical Society, which was presented at the February meeting of the council, the number of cases investigated in 1911 was 1244, against 1836 in 1910. The number of cases in which legal proceedings were instituted last year was 241, and, with few exceptions, penalties were paid by those against whom the proceedings were taken. In the majority of cases the offences were those of the sale of medicinal poisons, or the keeping of open shops for the sale of poisons by unqualified persons. In only 21 instances were proceedings taken against seedsmen or their assistants in 1911, whereas in the previous year 64 seedsmen and 39 assistants to seedsmen were proceeded against, which goes to show that licensed poison sellers are becoming acquainted with their obligations. In administering the Acts it is sometimes brought to the notice of the registrar that unqualified drug store keepers, in order to evade the Pharmacy Acts, sell preparations which should contain poisons from which the poison has been omitted. Last year

11 such cases were reported, and in two instances the sellers were summoned for infringement of the Merchandise Marks Act and fined. One of the defendants sold a preparation labelled "Laudanum—Poison," which contained no opium, an incident which shows the extremes to which an unqualified person will sometimes go in order to escape the penalty of infringing the Pharmacy Acts. The registrar's report also shows that the number of registered pharmacists in Great Britain is now 16,365, an increase of 73 on the preceding year. The membership of the society, which numbers nearly 7500, has never before been so large.

THE INTERNATIONAL OBSTETRICAL AND GYNÆCOLOGICAL CONGRESS.

A NATIONAL Organisation Committee for Great Britain and Ireland has been formed in connexion with the International Obstetrical and Gynæcological Congress, which is to be held in Berlin from Sept. 10th to 12th, 1912. The committee includes representatives from the Royal Society of Medicine (Obstetric and Gynæcological Section), North of England Obstetrical and Gynæcological Society, Edinburgh Obstetrical Society, Glasgow Obstetrical and Gynæcological Society, and the Royal Academy of Medicine in Ireland. The Central Organisation Committee in Berlin has decided to hold a formal discussion at the first session of the Congress on Sept. 10th, on the Surgical Treatment of the Peritoneum. The duties of the National Organisation Committee of Great Britain and Ireland are (1) to nominate delegates to the Congress for the United Kingdom, the number of official delegates being expressly limited by the Central Organisation Committee to three; and (2) to select a "*Rapporteur*" (not necessarily one of the three delegates) who will personally open the discussion on the Surgical Treatment of the Peritoneum as this country's representative and give the views held here on the subject. The secretaries of the National Organisation Committee are Mr. J. H. Targett, 19, Upper Wimpole-street, London, W.; and Dr. Walter W. Tate, 32, Queen Anne-street, London, W.

THE INCIDENCE OF CANCER IN FINLAND.

THE Cancer Commission which the Finnish Medical Society appointed to inquire into the incidence of cancer, including sarcoma, in Finland has now published a report[1] based on the answers received from 313 practitioners to the commission's queries as to the number and nature of cases under observation between Jan. 1st and March 31st, 1910. The inquiries were conducted on the same principle as in Sweden and Denmark, where similar investigations were held in the years 1905 to 1906, and 1908 respectively. The Finnish report shows that in several points there is a real or apparent difference in the incidence of cancer in the three countries. The value of the report is inevitably diminished by the diagnosis of cancer being in many cases uncertain, but it was confirmed by an operation or microscopic examination with sufficient frequency to illustrate the distribution of cancer in different parts of the country, and its relative frequency in different organs. In the towns the incidence of malignant disease for every 100,000 inhabitants was 28·38. In the country districts it was 16·37. This disparity is largely accounted for by the greater facility afforded the town dweller for medical attendance. The same explanation is probably also applicable to the difference between the total incidence of the disease in Finland, Sweden, and Denmark per 100,000, the figures being 18·14, 33·1, and 42·8 respectively, for the population is more dense and the patient is in closer contact with the physician in the latter countries. The frequency of the disease in men steadily increased with age till its maximum was reached at the age of 60. In women it increased till the age of 45 to 50; between the age of 50 and 55 it sank, and rose again to its maximum at the age of 55 to 60. Cancer of the lip represented 24·49 per cent. of the total in the male, while in the female it was only 3·21 per cent. Cancer of the stomach was more evenly distributed between the sexes, being 41·23 per cent. in the male and 37·18 per cent. in the female, in whom the frequency of cancer in the breast and uterus was 19·23 and 17·95 per cent. respectively. Altogether there were 244 cases of cancer and sarcoma in the male, and in the female 312, of which 116 involved the breast or uterus. No conclusive observations as to heredity, infection, local conditions, trauma, the influence of other diseases and of operations are made, nor is any new light thrown on the relation between cancer and various occupations; but the curious fact was noted that cancer was relatively less frequent in the upper than in the lower class of society, although the facilities for detecting the disease are presumably greater in the former than in the latter class.

[1] Finska Laekaresaellskapets Handlingar, November, 1911.

PRESERVATIVE TRICKS.

THE wily attempts of some persons to escape the vigilance of those responsible for the efficient administration of our food laws are well illustrated in a report recently published by the Local Government Board upon the analyses and methods of detection of certain proprietary substances sold as preservatives. Dr. G. W. Monier-Williams has found, for example, that a new preservative, sold under the name of "mystin," for preserving milk and cream has recently been advertised as possessing the advantage that its presence cannot be detected by analysis. A sample of mystin on analysis proved to contain sodium nitrite 9·85 per cent., formaldehyde 0·30 per cent., and water 89·85 per cent. As Dr. Monier-Williams points out, sodium nitrite is a dangerous drug with a powerful action on the heart. According to the directions given the addition of this compound to milk would mean that a quart of it would contain two grains of the nitrite, which is the maximum dose of this substance. Further examination of the milk so preserved brought the fact to light that the milk did not respond to the test most generally relied upon by analysts for the detection of formaldehyde in milk, so that in the ordinary routine examination of milk samples for preservatives such a sample might be passed as genuine. Moreover, the presence of nitrite of sodium in milk has not hitherto been suspected. Dr. Monier-Williams finds that the nitrous acid can be destroyed by heating the acidified milk with a little urea, after which it gives the formaldehyde reaction readily enough when that preservative is present. Reference in the report is also made to another proprietary preservative called "acoine" which contains sodium benzoate and sodium carbonate. Fluorides and sulphites are also offered as preservatives for milk products. The detection of the latter is easy, but the detection of fluorides is troublesome. Dr. Monier-Williams points out, however, the value of the titanium test, which depends upon the bleaching action of fluorine compounds upon a peroxidised titanium solution, the orange-yellow colour of which is partially discharged in the presence of fluorine compounds. It is obvious that these reports, which are issued from time to time by the Local Government Board must be of the greatest possible assistance to the analytical machinery of the Food and Drugs Acts. A question, however, which deserves very careful consideration, is whether it would not be better to control these

practices by sampling articles in the possession of the vendor, instead of relying upon the detection of preservatives in milk or cream as sold to the consumer. We have frequently pointed out the unsatisfactory position of the preservatives question, inasmuch as although regulations in regard to their use have been recommended by a departmental committee, no definite steps have been taken by the State. We believe, however, that the Local Government Board has for some time been giving close attention to the subject, and before long it is hoped that an official scheme, providing for the control of the use of preservatives in food, will be issued.

WE regret to announce the death on the night of Feb. 8th of Sir William Henry Allchin, M.D. Lond., F.R.C.P. Lond., physician extraordinary to the King and consulting physician to Westminster Hospital. A memorial service was held in the chapel of Westminster Hospital on the morning of Feb. 15th. We shall publish an obituary notice of Sir William Allchin in our next issue.

Mr. Lewis Harcourt, the Secretary of State for the Colonies, will address a meeting of the supporters of the London School of Tropical Medicine which will be held at the Mansion House, under the presidency of Sir Thomas Crosby, M.D., the Lord Mayor of London, on Wednesday, Feb. 28th, at 3 o'clock.

A DINNER was given on Thursday, Feb. 8th, at the Hotel Cecil, by the colleagues, old students, and former pupils of Sir Thomas Barlow and Mr. Rickman J. Godlee, as a compliment to the Presidents of the Royal English Colleges of Physicians and Surgeons. The chair was taken by Sir John Tweedy, and about 150 attended a very successful dinner.

Lieutenant-Colonel Sir Richard Havelock Charles, K.C.V.O., Serjeant-Surgeon to the King, and Fleet-Surgeon Robert Hill, M.V.O., R.N., Fleet-Surgeon to the *Medina*, have been promoted, respectively, Knight Grand Cross and Commander of the Royal Victorian Order. Lieutenant-Colonel Robert Bird, C.I.E., Professor of Surgery in the Medical College at Calcutta, and Mr. William Turner, M.D. Edin., Surgeon to the Colonial Hospital at Gibraltar, have been appointed Members of the Royal Victorian Order.

A MEETING of the Organisation Committee of the Seventeenth International Congress of Medicine will be held on Monday next at 5 P.M., in the Library of the Royal College of Physicians of London. We understand that H.R.H. Prince Arthur of Connaught has consented to open the Congress, and that the following have consented to give general addresses: Professor Chauffard (medicine), Professor Harvey Cushing (surgery), and Professor Ehrlich (pathology).

Sir George Hare Philipson, the President of the Newcastle College of Medicine, has been appointed by the Senate Vice-Chancellor of the University of Durham.

Surgeon-General W. B. Bannerman, I.M.S., late Director of the Bombay Bacteriological Laboratory, and now of the Madras Presidency, has telegraphed to Sir Ronald Ross, professor of tropical medicine in the University of Liverpool, that Captain W. S. Patton, I.M.S., assistant director of the King Institute of Preventive Medicine, Madras, has discovered the complete development of the parasite of kala-azar in Indian and European bed bugs.

AN EXAMINATION OF THE MEDICAL PROVISIONS OF THE NATIONAL INSURANCE ACT.

BY WILLIAM A. BREND, M.A. CAMB., M.B., B.SC. LOND.,
OF THE INNER TEMPLE, BARRISTER-AT-LAW; LECTURER ON FORENSIC MEDICINE, CHARING CROSS HOSPITAL.

II.[1]

The Benefits.

THESE are defined in Section 8, Subsection (1) of the Act, which commences with the important words qualifying the whole subsection: "Subject to the provisions of this Act the benefits ..... are ....."

Medical benefit.—"Medical treatment and attendance, including the provision of proper and sufficient medicines, and such medical and surgical appliances as may be prescribed by regulations to be made by the Insurance Commissioners."

The first point to notice is that nowhere in the Act is any indication directly given of what is meant by the words "medical attendance and treatment." In the ordinary sense medical treatment includes a great deal more than the services usually rendered by general practitioners. It embraces forms of treatment, such as the performance of major operations, determination of errors of refraction, and pathological investigations, which can only be given by those who have acquired special knowledge; as well as therapeutic measures which, though given under the orders of a medical man, would not actually be carried out by him—for example, sick-nursing, courses of massage, Weir-Mitchell treatment, &c. The question therefore arises, Is an insured person entitled to full medical attendance and treatment of every kind for any affection or injury, save maternity, from which he or she may be suffering? That is, such treatment as would be received under ordinary circumstances by a person to whom expense was no consideration. If not so entitled, to what extent is the treatment and attendance limited?

That the Act contemplates insured persons receiving some of the special forms of treatment indicated above may be inferred from other sections. Section 21, for instance, runs:—

> It shall be lawful for an approved society or Insurance Committee to grant such subscriptions or donations as it may think fit to hospitals, dispensaries, and other charitable institutions, or for the support of district nurses, and to appoint nurses for the purpose of visiting and nursing insured persons, and any sums so expended shall be treated as expenditure on such benefits under this part of this Act as may be prescribed.

This is a permissive section, but it is legitimate to infer that such subscriptions will not be granted unless the hospitals are utilised for the reception of insured persons, presumably surgical and serious medical cases. It is important to notice that the cost of neither this nor nursing necessarily comes out of the sum allocated for medical benefit. In Section 14, dealing with the rules which approved societies are empowered to make for the administration of sickness, disablement, and maternity benefit, we find "(2) no such rule shall prescribe any penalty ..... on account of the refusal by any such person to submit to a surgical operation or vaccination or inoculation of any kind, unless such refusal in the case of a surgical operation of a minor character is considered by the society or on appeal to the Insurance Commissioners, unreasonable." Clearly, again, the performance of both major and minor surgery is contemplated.

On the other hand, Section 15, which deals with the administration of medical benefit, shows that the Commissioners have discretionary powers. The essential clauses are—

> 1. Every Insurance Committee shall for the purpose of administrating medical benefit, make arrangements with duly qualified medical practitioners in accordance with regulations made by the Insurance Commissioners.
> 2. The regulations made by the Insurance Commissioners shall provide for the arrangements made being subject to the approval of the Insurance Commissioners and being such as to secure that insured persons shall, save as hereinafter provided, receive adequate medical attendance and treatment from the medical practitioners with whom arrangements are so made.....

[1] Article I. was published in THE LANCET of Feb. 10th, p. 383.

Then follow the clauses dealing with the preparation of lists of medical men to attend insured persons, and the section continues:—

> Provided that, if the Insurance Commissioners are satisfied after inquiry that the practitioners included in any list are not such as to secure an adequate medical service in any area, they may dispense with the necessity of the adoption of such system as aforesaid as respects that area, and authorise the Committee to make such other arrangements as the Commissioners may approve; or the Commissioners may themselves make such other arrangements as they think fit.....

It will be noticed that the word "adequate" is used twice in this section, but no indication is given of the meaning to be attached to it. Apparently the Commissioners are to be the sole judge of what is or is not adequate medical attendance and treatment, and they may be influenced by considerations other than those purely medical. The arrangements are to be made with "duly qualified medical practitioners.' If this meant *general* practitioners clearly the service would be limited to such treatment as they could give, and would, as a rule, exclude major surgery. But consultant physicians and surgeons are undoubtedly also "medical practitioners," and the Commissioners might consider a service inadequate which did not include a certain number of such upon each panel, or they might feel constrained to make additional arrangements for the performance of surgery and other special services.

The above considerations have been brought forward for the purpose of showing how extremely indefinite the Act is on the question of medical treatment and attendance, and how wide the powers of the Commissioners are. Until the regulations are published, it will be impossible to determine the services which are to be performed by medical men, and how far hospitals and other institutions will be utilised to reduce the amount of attendance necessary. Further, the profession is not justified in assuming that remuneration will come to them only out of the fund for medical benefit. While, as shown above, part of the actual medical treatment may be paid for out of other funds, services may be required from medical men in connexion with each of the other benefits for which they will be fully entitled to demand remuneration.

Suspension of Medical Benefit.

It is convenient here to consider what is likely to be the immediate consequence should medical practitioners decline to enter into contracts under the Act.

Section 15 provides that when in any area the Commissioners consider the service inadequate they "may suspend the right to medical benefit in respect of any insured persons in the area for such period as they think fit, and pay to each such person a sum equal to the estimated cost of his medical benefit during that period, and, where the Commissioners take any such action, themselves they shall retain and apply for the purpose such part of the sums payable to the Insurance Committee in respect of medical benefit as may be required."

An insured person will accordingly receive his money equivalent of medical benefit and will go and make his own arrangements for medical attendance, in most cases through the Friendly Society of which he is a member. Will not this be, in effect, largely reverting to the position which existed on the introduction of the Bill—viz, control of medical benefit by friendly societies? However just the opposition to the Act, the profession has no fresh cause of quarrel with Friendly Societies. Medical officers of such institutions might refuse to take new members at the old rates, but many are under contracts as regards existing members which they would find difficult to break. The experience of the past in the matter of Friendly Society appointments and united action has not been very encouraging.

Sanatorium Benefit.

"Treatment in sanatoria or other institutions or otherwise when suffering from tuberculosis, or such other diseases as the Local Government Board with the approval of the Treasury may appoint." In Section 16 it is amplified to include (*a*) treatment "in sanatoria and other institutions, with persons or local authorities (other than poor law authorities) having the management of sanatoria or other institutions approved by the Local Government Board"; and (*b*) treatment "otherwise than in sanatoria or other institutions, with persons and local authorities (other than poor law authorities) undertaking such treatment in a manner approved by the Local Government Board."

The administration of sanatorium benefit is in the hands of the Insurance Committees, but the arrangements must be "to the satisfaction of the Insurance Commissioners." A million and a half sterling is available for the founding of institutions under the direction of the Local Government Board, and a million annually for their maintenance.

It will be seen that the widest possible latitude is allowed as to the methods of procedure to be followed. Sanatoria in the limited sense of the word and hospitals for advanced cases may be built and maintained. Anti-tuberculosis dispensaries may be established in every district. There is nothing in the Act to prevent such institutions being staffed by local medical men, nor is there any reason why all the practitioners on a panel should not be recognised by the Insurance Committee as persons "undertaking treatment" within the meaning of Section 15, providing the treatment is in a manner approved by the Local Government Board. In view of the frequency of tuberculosis this opens up important possibilities. It would be quite legal for arrangements to be made whereby a general practitioner continues to treat a case of tuberculosis himself, but is able to command the assistance of a local antituberculosis dispensary for making bacteriological and other investigations and applying special forms of treatment. The person so treated would become the recipient of sanatorium benefit and the Insurance Committee would have the power of paying his medical attendant a fee from the fund available for sanatorium benefit in respect of him. It is, indeed, in the best interests of the service that medical men on the panel should be closely in touch with the administration of sanatorium benefit, for by that means early and efficient treatment of cases of tuberculosis will be secured.

Maternity Benefit.

The Act imposes no obligation upon a woman to be treated by a medical man during parturition. The benefit, a sum of 30*s*., is to be administered by approved societies, and may be in cash or otherwise. Medical men will treat such persons as private patients, but presumably they will demand higher fees from those in receipt of maternity benefit than they now get.

There is a curious provision in Section 18. The last paragraph, after stating that a woman shall have the choice of being attended by a medical practitioner or midwife, continues: "but if, in the case of a midwife being selected, a duly qualified medical practitioner is subsequently summoned in pursuance of the rules made under the Midwives Act, 1902, the prescribed fee shall, subject to regulations made by the Insurance Commissioners, be recoverable as part of the maternity benefit." It is not clear what is meant by the words "prescribed fee." No fee is mentioned in the Midwives Act, and as the arrangement will be a private one between doctor and patient in maternity cases, the Insurance Commissioners will not have the power to prescribe a fee. Under existing arrangements local authorities have agreed in some instances to pay a fee, usually of 1 guinea, to medical men called in under the Act. As the cases are specially difficult medical men have long felt that this remuneration is inadequate, and they would be fully justified in declining to treat insured persons under such circumstances at that fee.

Some interesting problems are likely to centre round the meaning to be attached to the word "confinement." Presumably it will not apply to expulsion of the uterine contents during the early months of gestation. It will be necessary therefore to fix a stage of development of the fœtus, after which the uninsured wife of an insured man will be able to claim maternity benefit. The same point will determine when an insured woman will be entitled to medical benefit for abortion, and when to maternity benefit. If any such rule as that which applies in the case of the Notification of Births Act—viz., 28 weeks' development—be adopted, difficulties will arise in practice. Theoretically, such a dividing line is excellent; practically, it cannot be determined without a considerable margin of error. In the case of the Notification of Births Act it does not seriously matter if a certain number of notifications of births under 28 weeks gestation are made. When the question of medical or maternity benefit is involved the circumstances will be more closely scrutinised. One can imagine the case where, in an uninsured woman, it has been decided to induce premature labour. If done to-day she receives no benefit; if postponed till next week, though perhaps prejudicial to her health, she receives maternity benefit.

Sickness and Disablement Benefits.

Sickness benefit is the right to periodical payments "whilst rendered incapable of work by some specific disease or by bodily or mental disablement." Disablement benefit is the right to payments after the termination of sickness benefit "so long as so rendered incapable of work by the disease or disablement."

These benefits are to be administered by approved societies, and do not, as far as the Act is concerned, directly affect medical men, since their contracts will only be with Insurance Committees. But it is obvious that for the proper discharge of their obligations approved societies will have to seek the assistance of medical practitioners. Medical certificates will be required to prove that persons are incapable of work from disease or disablement, and repetitions of these certificates at intervals so long as either benefit is claimed. Such certificates are not in the nature of medical treatment, and they impose legal responsibilities upon the persons who give them, possibly entailing attendance at civil or criminal courts. Medical men would, therefore, be justified in demanding fees for them, which would presumably be paid out of the funds available for sickness and disablement benefit. Nor are these the only medical services which may be required by approved societies. The section previously quoted places with them the obligation of determining, not only when refusal to submit to a surgical operation is "unreasonable," but what constitutes "minor" surgery. Further, the societies may make rules suspending the payment of sickness or disablement benefit on the ground that the disease or disablement has been caused by the misconduct of the person claiming the benefit. It is not likely that approved societies will settle these matters by the aid of lay opinion only.

Free Choice of Doctor.

Section 15 provides that an insured person may select from a list of medical practitioners the practitioner by whom he wishes to be attended, subject to the consent of that practitioner to attend him. The right of a practitioner to refuse persons is not absolutely unlimited, for persons who have been refused are to be distributed among the practitioners on the list, and thus a person who had been refused by every doctor would, in the end, come to one who had declined him. However, the distribution is to be made as far as possible by the practitioners themselves, and the number of such cases is not likely to be great.

A more important clause in this section is that which embodies what is known as the "Harmsworth" amendment. It provides that where persons are receiving medical attendance and treatment under any system or through any institution existing at the time of the passing of the Act such medical attendance and treatment, if approved by the Insurance Committee and Commissioners, may be treated as, or as part of, medical benefit; but no person is to be deprived under this clause of his right, if he so elects, to choose his own medical attendant.

It has been said that this provision will perpetuate the existence of institutes which provide medical attendance of an incomplete or unsatisfactory character among the poorer classes. But such a danger is probably sufficiently guarded against by the necessity of obtaining the approval of the Commissioners, and the retention by the members of the right of free choice of doctor. On the other hand, it safeguards the holders of certain existing appointments which nobody wishes to disturb. There are cases where medical men have been appointed by the management of firms or public companies to look after the health of their employés upon terms and conditions satisfactory to all parties. Such arrangements can thus be continued unchanged.

Control of the Medical Service.

The Bill when first introduced placed the administration of medical benefit in the hands of approved societies. By amendments made later it was assigned to the Insurance Committees. But owing to the constitution of these bodies it is argued that the administration will still be by approved societies, but under another name. Three-fifths of the total number are to be representatives of insured persons, and one-fifth is to be appointed by the county or borough council. Two members are to be elected by local medical practitioners, and one, two, or three medical practitioners are to be appointed by the County or borough council according to the size of the committee. The remaining members are to be appointed by the Insurance Commissioners.

If "administration" connoted "control" it is undoubted that the powers of the profession would be limited to stating their case. But perusal of the Act makes it clear that by far the largest element of control will rest with the Commissioners. In practically every matter the Committees have to act in accordance with regulations made by the Commissioners, and every arrangement has to receive the approval or consent of the Commissioners, including the arrangements made with medical practitioners and the administration of medical benefit. The Insurance Committees cannot remove a medical man from the panel, nor can they contract separately with any individual practitioner. For the protection of their interests, therefore, the profession should in the first instance look to the Insurance Commissioners. This body is required by the Act to set up as soon as possible an Advisory Committee to assist it in the framing of the regulations, and the medical profession has been promised an opportunity of nominating as members of the Committee medical men who have had personal experience of general practice. In view of the importance of the regulations, is it not a tactical mistake for the profession to decline to appoint these representatives? By making the appointments it does not in any way commit medical men to working under the Act, while if the regulations should prove unsatisfactory the profession is in a stronger position to win public support if it can say that no effort has been spared to make the present Act workable.

A local medical committee may be formed in each district, and, provided it is representative of the medical practitioners resident in that district, the Insurance Committee is required by the Act to consult it upon all general questions affecting the administration of medical benefit, including the arrangements made with medical practitioners. The constitution of these committees is left entirely to the medical men. They will be of value in helping to secure unanimity of action, not only in each district, but throughout the whole country. If formed in the first instance for the purpose, they will be able to appoint the local medical representatives upon the Insurance Committees. Medical committees will possess no direct controlling power, but their moral effect may be considerable. The lay members of an Insurance Committee will require strong justification to override the deliberately expressed wishes of the majority of the medical men in the neighbourhood.

The Insurance Commissioners may require the medical committees to perform other duties and exercise other powers. It is impossible to forecast these duties, but it would conduce to the efficiency of the service if they included the power to investigate cases of alleged malingering. They might well also be given the right to inquire into anything of the nature of unprofessional conduct by medical men, and to exercise, where necessary, modified disciplinary powers. While every medical man has a statutory right to be on the panel in his district (or, if necessary, on two or more panels), the power to remove a name rests solely with the Commissioners, who, however, cannot act until after inquiry. As the Act does not lay down any special form of procedure for the inquiry, the profession might quite reasonably ask that it should be in the first place conducted by the local medical committee.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—The next quarterly meeting of this association will be held at the London County Asylum, Long Grove, Epsom, on Feb. 22nd, under the presidency of Dr. W. R. Dawson. At 11 A.M. there will be an inspection of the buildings, when a description of the asylum and its heating and lighting arrangements will be given by Mr. T. G. Hine, the architect, and Mr. W. Clifford Smith, M.Inst.C.E., respectively. At 2.15 P.M. Dr. G. F. Barham and his colleagues will give a clinical demonstration of cases of interest; Dr. David Blair (Lancaster) will read a paper on Forced Feeding; and the following papers will, so far as time permits, be read by members of the medical staff at Long Grove: Dr. Barham, Insanity with Myxœdema; Dr. Bernard Hart, a case of Double Personality; Dr. Edward Mapother, Aphasia in General Paralysis and the Conditions Associated with It; and Dr. J. E. Martin, a case of Hysterical Hemianæsthesia with Torticollis and Talipes.

REPORT AND PAPERS ON EPIDEMIC POLIOMYELITIS.

THIS report, which has just been presented to the Local Government Board, is divided into five sections:—1. Dr. R. J. Reece on the Prevalence of Acute Poliomyelitis in Devonshire and Cornwall in 1911. 2. Dr. Reginald A. Farrar on Outbreaks of Disease affecting the Cerebro-Spinal System in the Midland Counties and in Dorsetshire, 1910. 3. Dr. Mervyn Gordon on Acute Poliomyelitis with Reference to its Etiology, Histology, and as to Immunity. 4. Dr. Mervyn Gordon on the Result of the Examination of Materials Received in Connexion with Dr. Reece's Inquiry in Devon and Cornwall. 5. Clinical and Epidemiological Notes on Epidemic Poliomyelitis, by Dr. Hugh A. Macewen.

The report is prefaced by an introduction by Dr. Newsholme, principal medical officer to the Board, and a copy of the memorandum on Acute Poliomyelitis circulated to the sanitary authorities in December, 1911.

Section 1: Outbreaks in Cornwall and Devon.

The attention of the Local Government Board having been called at the end of July, 1911, to several cases of illness which were considered to be of the nature of cerebro-spinal meningitis in the neighbourhood of Holsworthy in North Devon, Dr. Reece was sent down to investigate the matter.[1] He found that the illness was more widespread than had been at first suspected, and that cases occurred throughout Devon and Cornwall. A map is appended to the report which shows the distribution of the 154 known cases. Of these, 42 occurred in the rural district of Holsworthy, 17 in the Bideford district, 15 in South Molton district (all within a small radius of one another), and the remainder at various points throughout Devon and Cornwall. The list does not include the borough of Plymouth and Devonport, in which many cases were known to occur. Death took place in 34 of the 154 cases—a case fatality of 22·1 per cent., which is higher than most of the epidemics abroad, and, as the writer points out, is consistent with the view that the mild cases have escaped recognition.

A series of tables dealing with age-incidence, seat of paralysis, and time after the onset of disease at which death occurred are given, together with certain climatic, topographical, and industrial details. The clinical characters are analysed, and it is stated that examples of all the different types of the disease, as given by Wickman, were observed, except the "ataxic" type. The relative frequency of such symptoms as rise of temperature, headache, vomiting, convulsions, hyperæsthesia, anæsthesia, Kernig's sign, condition of reflexes, epistaxis, retraction of the head and neck, rashes, herpes, and sweating are given. It is interesting to note that in 14 cases definite hyperæsthesia is said to have been present, and in one case almost complete anæsthesia.

Kernig's sign was recorded as being present in 63 cases and absent in 41; in 50 cases there was no record. The writer of the report goes on to say: "As to whether it is elicited in certain cases must depend on the personal factor of the examiners; many persons in health cannot completely extend the leg on the thigh when the latter is flexed, and this fact leads to uncertainty with regard to Kernig's sign when the examiner has never examined a case where the sign is undoubtedly present." There seems some confusion here as to how the clinical sign should be elicited. It is, however, a matter of small importance, for Kernig's sign is of little or no diagnostic value. It is notable that the patellar reflex is only recorded in some 80 out of the 154 cases, and the condition of the plantar reflex is not recorded in precise terms. Herpes is described as occurring 7 times, twice in the form of herpes labialis. The report states that multiple cases in a household were met with in 11 instances. In 4 instances there were 2 cases, in 2 there were 3 cases, in 4 there were 4 cases, and in 1 instance 6 cases in a house.

The possible transportation of infection by an apparently healthy carrier is next dealt with, and a most interesting instance is given in which the father of a child with undoubted poliomyelitis apparently carried the infection to two children in an isolated farm ten miles distant. A second instance is given in which a nurse washed the body of a child who had died from the disease and subsequently attended a woman in her confinement. This woman on the sixth day after delivery had a series of convulsions associated with albuminuria and paralysis of the left arm. The diagnosis here of poliomyelitis is very arguable, for the case would seem more probably to be one of eclampsia. The examination of the cerebro-spinal fluid has been made in very few caess, as the reports say it has been most difficult to obtain these for examination. The report mentions the possibility of the disease occurring in animals, and gives facts with regard to the sudden death of two pigs and other animals in association with cases of the disease.

One of the most interesting features in the report is that of an epidemic disease which occurred at Stoke Rivers, a small village seven miles from Barnstaple, and was investigated by Dr. Harper and Dr. Adkins. (The cases in this epidemic are not included in the 154 cases mentioned above.) This village has 18 houses and a population of 119 persons. Of these, 61 were above school age, 43 attended school, and 15 were below school age. In this community 36 persons were attacked with illness—35 during the month of September and 1 in August; 9 other persons suffered in a minor degree. Of these 36 persons, 4 were over school age, 6 were under school age, and 26 were attending school. 14 out of the 18 houses in the village were affected.

The details afford most interesting reading. The illness was attended by headache, vomiting, sore-throat, fever, and diarrhœa. The absence of the knee jerk which attended or followed the illness was the most constant feature. In only three of these cases did paralysis occur. Two children had facial paralysis, and one lad, aged 17, had still on Oct. 8th "difficulty in standing."

Dr. Adkins says: "The facts are put on record for what they are worth." The writer of the Local Government report says it is difficult to resist the conclusion that certain of the cases above detailed were attacks of poliomyelitis. The conclusion is of course speculative, for among the whole 36 cases there is not a single case of definite poliomyelitis. It is admitted by all that facial paralysis, although occasionally a manifestation of poliomyelitis, is yet much more frequently due to some septic infection arising from the teeth or throat. Again, the case of the boy aged 17 with weakness of the legs cannot be accepted as an undoubted case of poliomyelitis. In none of the epidemics of poliomyelitis so far reported has the proportion of "abortive" cases amounted to 92 per cent. Neither have they failed to contain instances of the common type. Before accepting an epidemic with such unusual features as due to poliomyelitis, far more proof would be required, both with regard to the faucial conditions and also in regard to the cerebro-spinal fluid. Although we may be critical of the deductions, no one can fail to appreciate the admirable way in which the Stoke Rivers epidemic has been worked out.

Dr. Reece comments on the sanitary administration in Devon and Cornwall, and calls attention to the inadequate provision for dealing with infective disease in these two counties. Photographs of the "isolation hospital" of the urban and rural district council of Holsworthy are given. The difficulty of dealing with an infective person is shown by the case of a nurse who, taken ill during the performance of her duties, would, but for the kindness of the medical attendant who took her into his own house, have been left without a refuge.

Outbreaks in Midland Counties and Dorset.

The second section deals with an outbreak of disease affecting the cerebro-spinal system in the Midland counties and an epidemic of poliomyelitis in Dorset in 1910. The cases occurred in Nottingham and in the Melton Mowbray district. Information was obtained with regard to 83 cases; 11 of these occurred in the city of Nottingham. Of these 11 cases 6 were fatal; 1 on post-mortem examination was a case of streptococcal meningitis, another probably tuberculous meningitis, and in 6 a "Gram-negative" diplococcus was found. Dr. Farrar concludes that there were 8 cases occurring in Nottingham and 1 at Barlestone which must be regarded as true cerebro-spinal fever, leaving 74 cases which belong to a different category. He gives good reason for regarding these 74 cases as poliomyelitis, since practically all had localised paralysis of a muscle or groups of muscles, and as he points out this is a characteristic feature of poliomyelitis and a rare manifestation of cerebro-spinal fever. He also notes the age-incidence

[1] THE LANCET, Sept. 16th (p. 843) and 23rd (p. 896), 1911.

and the occurrence of the disease during the summer in support of the view that they were cases of poliomyelitis. In only 9 cases was the cerebro-spinal fluid withdrawn by lumbar puncture, and in only 4 of these was it examined, and in all of them an excess of polynuclear leucocytes was present, which would seem to point to a meningitis. In conclusion, Dr. Farrar says that pathological investigation, so far as it was carried out in respect to the 74 cases under consideration, gave no support to the view that any of these were cases of cerebro-spinal fever, and he has no hesitation in concluding that the outbreak was one of epidemic poliomyelitis, and not of cerebro-spinal fever.

The outbreak at Cerne Abbas and Up Cerne in Dorset occurred between Sept. 29th and Oct. 21st, 1910. In these little hamlets 16 cases occurred with 2 deaths. The history of these cases is given in detail. Multiple attacks occurred in three households—viz., three cases in one household and two in each of the others. The cerebro-spinal fluid was not examined in any case. The origin of the outbreak could not be discovered, but the village is a frequent resort of visitors from Dorchester and Weymouth.

Experimental and Pathological Investigations.

In the third section Dr. Mervyn Gordon gives a good digest of the work on experimental poliomyelitis in monkeys, and details as to the nature of the virus. He states that the recognition of poliomyelitis in fatal cases is easy, owing to the very characteristic histological lesions which occur in the cord. He gives a table showing the chief points of distinction between a meningococcal meningitis, a septic meningitis, a tuberculous meningitis, and a poliomyelitis.

In the fourth section Dr. Mervyn Gordon gives the results obtained from examination of material received from the cases in Devon and Cornwall. He states that the cells present in the cerebro-spinal fluid were lymphocytes, but he does not give the number of specimens examined. He suggests that the retention of the capacity of the cerebro-spinal fluid in poliomyelitis to reduce Fehling's solution may be of value in the distinction between the cerebro-spinal fluid of poliomyelitis and that of tuberculous meningitis. A series of excellent photographs are given illustrating the changes found in cases of acute poliomyelitis. He acknowledges his indebtedness to the courtesy of Professor Levaditi, of Paris, for the animal experiments he has carried out with the material from this outbreak. Professor Levaditi reported that two monkeys injected with emulsions of the cord from two cases developed typical poliomyelitis.

Clinical and Epidemiological Aspects.

The fifth section is a digest of the clinical and epidemiological aspects of acute poliomyelitis compiled by Dr. Macewen from various sources.

Dr. Newsholme in his introduction notes the importance of watching for the occurrence of epidemic poliomyelitis in England in order to take a suitable opportunity to make a comprehensive study of its clinical and epidemiological characters. He summarises the facts which have already been given in the above report, and states that "it is evident that much further research work is needed both in the laboratory and by exact and painstaking inquiry into the circumstances of local outbreaks, with a view to the more exact determination of means of communication of this disease, and to the discovery of practically available methods of recognising the presence of infection in early cases of suspected disease, and in contact with known cases of the disease."

EIGHTH CONGRESS OF THE GERMAN ROENTGEN SOCIETY.—This Congress will take place at Berlin (Langenbeckhaus) on Sunday, April 14th, commencing at 9 A.M. punctually. On the previous evening at 8 P.M. any projections which may be necessary to show in connexion with the next day's papers will be then exhibited in order to unburden the proceedings on the Sunday. Papers and demonstrations must be sent before March 1st to Herr Dr. Immelmann, Lützowstrasse, 72, Berlin, W. 35. Communications with respect to membership and subscriptions should be made to Herr Melzer, Ziegelstrasse, 10/11, Berlin, N. 24. Dr. A. Köhler, of Wiesbaden, is the President for the year 1912.

VENTILATION AND OZONE.

AT a meeting of the Royal Society of Arts held on Feb. 7th, Lord Sanderson being in the chair, Dr. Leonard Hill read a paper entitled "The Influence of Ozone in Ventilation."

Chemical Purity of the Air.

At the commencement of the paper, which was a joint communication by himself and Dr. Martin Flack, and occupied about an hour in delivery, Dr. Hill said that the good effects which resulted from efficient ventilation and open-air treatment were generally supposed to be due to the chemical purity of the air, but this was an error, because the effects in question were really due to the movement, coolness, and relative humidity of the air, and to the ceaseless variations of these qualities. The chemical purity of the air could be considered from three points of view—namely, the concentration of carbon dioxide, the concentration of oxygen, and the supposed presence of organic poison exhaled in the breath.

Concentration of Carbon Dioxide.

It was an error to imagine that respired air was rendered poisonous by the presence of carbon dioxide in amounts exceeding a very few parts per 1000. The truth of the matter was quite otherwise, for whatever the percentage of carbon dioxide in the atmosphere might be, that in the pulmonary air was kept constant at about 5 per cent. of an atmosphere by the action of the respiratory centre. At each breath a person rebreathed into his lungs the air in the nose and large air-tubes (the dead space air), and about one-third of the air which was inhaled into the lungs was "dead space" air. This re-breathing of one's own breath was a natural and inevitable performance for both human beings and the lower animals. By a series of observations made on rats confined in cages with small ill-ventilated sleeping chambers Dr. Hill and Dr. Flack found that the temperature and humidity of the air—not the carbon dioxide and oxygen concentration of the air—determined whether the animals stayed inside the sleeping chamber or came outside. If the air was cold they stayed inside, even when the carbon dioxide rose to 4 or 5 per cent. of an atmosphere. When the sleeping chamber was made too hot and moist they came outside.

In breweries the men who tended the fermentation vats worked for long hours in concentrations of carbon dioxide of 0·5 to 1·5 per cent., and such men were no less healthy and long-lived than those engaged in other processes of the brewing trade. It was only at higher concentrations of carbon dioxide, such as 3 to 4 per cent. of an atmosphere, that the respiration was increased so as to become noticeable to the individual himself; the limit of panting was then soon reached and the power to do work was checked. Divers who followed their occupation in diving dresses and men employed in compressed-air caissons constantly worked in concentrations of carbon dioxide higher than 1 per cent. of an atmosphere, and so long as the carbon dioxide was kept below 2 to 3 per cent. of an atmosphere they were capable of doing efficient work.

Concentration of Oxygen.

Turning now to the question of the percentage of oxygen present in inhaled air, Dr. Hill said that the oxygen in the worst ventilated schoolroom, chapel, or theatre was never lessened by more than 1 per cent. of an atmosphere, but in all the noted health resorts of the Swiss mountains, such as St. Moritz, the concentration of oxygen was considerably less than this. In Potosi, a city of 100,000 inhabitants at an altitude of 4165 metres in the Andes, the barometric pressure was only about 450 millimetres of mercury, but the people nevertheless displayed great agility in dancing and in bull-fights. Dr. Hill and Dr. Flack had watched students shut up in an air-tight chamber until they came to breathe air containing 3·5 per cent. of carbon dioxide and only about 16 per cent. of oxygen—air in which they found they were unable to light a match and smoke a cigarette. There was then too low a percentage of oxygen to support combustion, but of this the occupants of the chamber were quite unaware. All the evidence went to show that it was only when oxygen

was lowered below a pressure of 14 to 15 per cent. of an atmosphere that signs of bodily distress for want of oxygen arose.

Supposed Presence of Organic Poisons.

The facts already mentioned with regard to the atmosphere in which certain brewery workers, caisson workers, and divers followed their occupation proved that concentrations of carbon dioxide such as occurred in the most crowded and worst ventilated rooms were not directly injurious to health. Forced to admit this, the hygienist has fallen back on the hypothesis that organic chemical poisons were exhaled in the breath, and that the percentage of carbon dioxide was a valuable guide to the concentration of these. It was necessary, said the hygienist, to keep the carbon dioxide below 0·1 part per 1000, so that the organic poisons might not collect to a harmful extent. The supposed existence of organic chemical poison in the expired air was based upon experiments made by Brown-Séquard and d'Arsonval, who injected into guinea-pigs and rabbits either the condensation water obtained from the breath or water which they had used several times over to wash out the trachea of dogs. The water was injected subcutaneously and in large amounts, and produced in their hands signs of illness, collapse, and death. A few confirmatory results have been obtained by some experimenters who used such absurd methods of investigation as to collect condensation water by breathing through a cooled flask and to inject 1 or 2 cubic centimetres of this fluid into a mouse weighing about 13 grammes, a proceeding equivalent to injecting 5 litres of water into a man weighing 65 kilogrammes. Who would not be made ill by the injection of about 9 pints of cold water beneath his skin? The experiments of Brown-Séquard and d'Arsonval have been repeated by many others, and with negative results by those whose methods of work demand most respect—Dastre and Loye, Van Hofmann, Wellenhof, Lehmann and Jessen, Haldane and Smith, and Weir Mitchell and Borgey.

Brown-Séquard and d'Arsonval in their experiments either (1) gave intravenous or subcutaneous injections of condensation water from the breath or washings from the trachea, or (2) they kept animals in cages communicating in series, a current of air being drawn throughout the entire length of the series. Dr. Hill and Dr. Flack suggested that the deaths of injected animals were due either to the excessive amount of the fluid injected or to the inclusion in it of droplets of saliva which produced the well-known phenomena of the anaphylactic shock. Anaphylaxis signified the condition in which an animal became sensitised by the subcutaneous injection of a protein derived from an animal of a different species, and an animal thus sensitised might be poisoned by a subsequent injection of the same protein. When the animals in the last of the series of cages died, the fatal effect was probably due to suffocation from the proportion of carbon dioxide in the air having been allowed to rise to 10 or 12 per cent. Dr. Hill and Dr. Flack, after studying the literature of the subject and making various experiments, have come to the conclusion that there was not at present any trustworthy evidence of the presence of organic chemical poisons in exhaled air.

Effects of Electric Fans.

They enclosed eight students in a small chamber holding about three cubic metres of air and kept them therein until the carbon dioxide had reached 3 or 4 per cent. and the oxygen had fallen to 17 or 16 per cent. The wet-bulb thermometer rose meanwhile to about 85° F. and the dry-bulb thermometer to one or two degrees higher. The discomfort was very great, but this was relieved to an astonishing extent when electric fans placed in the roof were set in motion, whirling the air in the chamber, and so cooling the bodies of the students. In a crowded room the air confined between the bodies and clothes of the people was almost warmed up to body temperature and saturated with moisture, so that cooling of the body by radiation, convection, or evaporation became nearly impossible. This led to sweating, wetness and flushing of the skin, and a rise of skin temperature. The blood was sent to the skin and stagnated there instead of passing through the brain and viscera. Hence arose the feelings of discomfort and fatigue, but the fans whirled away the layer of stationary wet air round the students' bodies, replacing it by the somewhat cooler and drier air in the rest of the chamber, and so relieved the heat stagnation from which they suffered.

Prophylaxis of Catarrhal Infections.

Catarrhal infections of bacterial origin were spread by the expulsion of droplets of saliva during the acts of speaking, coughing, or sneezing, and could not be prevented by ventilation. The true prophylactic against such infections was the avoidance of whatever might diminish the natural immunising power of the animal organism. Exposure to overheated dry air dried up not only the skin but the membranes of the nose and throat, and so lessened immunity. Exposure to overheated moist air brought the blood into the skin, lessened the circulation through the viscera, and decreased the evaporation from the respiratory tract; the system also suffered from the absence of the stimulating effect of cold on the cutaneous nerves. Hence arose diminished health and strength together with increased susceptibility to catarrh. Those who habitually exposed themselves to cold rarely took cold. Confinement in overheated stagnant air, which too often pervaded places of business and amusement, was one of the chief causes of the depressed physical and mental vigour of town dwellers.

Properties of Ozone.

Dr. Hill here showed an automatic ventilating fan to be inserted in the window of an apartment; at temperatures below 60° F. it remained closed but above 60° it remained open. He also showed some ozone-generating apparatus of the Ozonair Company. Each complete element of this apparatus consisted of a thin sheet of micanite covered on each side by a square of gauze made of an aluminium alloy and having 40 meshes to the inch. Ozone was produced by the silent discharge of a high-tension electric current from one sheet of gauze to the other across the micanite. Mammals exposed to different concentrations of ozone in a closed chamber were killed by prolonged breathing of an atmosphere containing about 20 parts of ozone per 1,000,000 parts of air, the cause of death being an acute irritative inflammation of the respiratory tract. The ozone in such concentrations made the eyes water and caused coughing. When ozone was employed in ventilation it was arranged so as to produce none of these symptoms of irritation. Ozone could be used in high concentrations for sterilising water, this being one of its most valuable applications. It also destroyed all disagreeable smells. Ozone itself had a peculiar odour, which could be perceived by the nose in concentrations of far less than 1 part in 1,000,000, and for continuous breathing it should be present in concentrations not greater than that which was scarcely perceptible by the nose. Its powerful deodorising properties made it useful in places where offensive trades were carried on, and in improving the atmosphere of tube railways.

MEDICINE AND THE LAW.

Thirty Years of Unqualified Practice.

BEFORE the stipendiary magistrate at Leeds, William Henry Gisburne Bowell, 72 years of age, was recently charged upon five summonses with offences under Section 40 of the Medical Act of 1858, and having been convicted upon one was fined £10, including costs, the other four charges not being proceeded with. Section 40, it will be remembered, is directed against persons who falsely and wilfully pretend to be qualified medical practitioners, the taking or using of titles implying medical qualifications being a manner of committing the offence specially mentioned in the section in the form of an alternative. The career of the defendant has been somewhat remarkable, for he has apparently been generally regarded among his lay neighbours for many years as a qualified medical practitioner, although, presumably, such medical men as were aware of his existence knew that his name was not on the Medical Register.

In the case which was gone into before the magistrate the defendant's lack of qualification and his readiness to give certificates in his assumed character of medical practitioner were brought to light by the naval authorities at Sheerness in a manner unfortunate for the patient implicated in the transaction. A young seaman in the Royal Navy had gone to Leeds on furlough, and on the

way there had injured his knee. Desiring to prolong his leave on account of his injury, he obtained a certificate to that effect from Bowell, paying him a fee of half-a-crown. When it was noticed that the signature upon the certificate was not that of a registered practitioner the young sailor was punished for his action in presenting it by a fine and the loss of a stripe. Apparently the defendant had described himself in a local directory as a medical practitioner and surgeon, and had been acting as surgeon to a Friendly Society's lodge. It was urged on behalf of Bowell, who admitted his offence, that he had assisted an uncle, a qualified practitioner, in his practice from 1859 to 1874, and after that had done the same for a nephew, who succeeded the uncle, from 1874 to 1881, so that he had a lengthy experience. Since 1881 he had practised on his own account without anyone interfering with his doing so, but apparently not with any great success, as he was described by his advocate in an appeal for leniency as being in very poor circumstances. The fine ordered to be paid is half the maximum penalty allowed by the section, and under the conditions indicated will no doubt prove sufficient to prevent the repetition of the illegalities, but the case was not one where mercy was called for.

The local Friendly Society can hardly be congratulated upon the care exercised by it in the choice of a medical attendant for its members; but bone-setters and herbalists have been employed, we believe, by some clubs at the direct instance of their members. An interesting part of the case is the trouble that was brought upon the injured man, whose plight is a hard one. Bowell seems to have been absolutely accepted by the local community as a medical man, and the unlucky seaman went to him in all good faith.

The Chairman of the London County Council and the Council's By-laws.

Mr. Edward White, J.P., chairman of the London County Council, was summoned recently at Marylebone police court by the Marylebone borough council for having constructed at his residence in Upper Berkeley-street soil-pipes of iron instead of drawn lead with proper wiped plumber's joints, as required by by-laws of the London County Council, made under the Metropolis Management Acts of 1855 and 1899, and also for having the work carried out without having previously deposited "plans, sections, and particulars" of it with the borough council. After evidence had been given, and the point had been raised by Mr. White that to constitute an infringement of the by-law the soil pipe complained of must be inside the house, whereas a very small portion of it only was so situated, Mr. Plowden held that the by-law did not contemplate a pipe such as that in question, and that as the council had not satisfied him that the whole pipe was inside the house they could not succeed upon that point. With regard to the failure to deposit plans, he decided in favour of the council and against the defendant, whom he fined 10*s.* with 2*s.* costs. Mr. Plowden does not appear to have taken a very serious view of an offence by the chairman of the body responsible for the sanitation of the County of London against its sanitary by-laws. Nor does Mr. White himself appear to have expressed himself with any very great respect for the regulations made in the interest of the public health by the Council over which he presides, if Dr. C. Porter, medical officer of health of the Borough of Marylebone, is correctly reported to have said in evidence that when he called Mr. White's attention to the matter of the soil pipe he received the reply from Mr. White, who seemed surprised, that he "had had something to do with the passing of the by-laws and thought that some of them were a little silly." It can hardly be encouraging to a borough council in its efforts to secure proper sanitary conditions within its area to find the chairman of the Council of the metropolis describing that Council's own regulations, which it is the duty of the local authority to enforce, as "silly." Nor is a medical officer of health likely to find his own duties rendered more easy to perform by such a pronouncement. If the chairman of the London County Council considers its by-laws silly or not worth attention, his proper course would seem to be to obtain, or to endeavour to obtain, their amendment. Of course, we quite agree that Mr. White's default was only technical, and sympathise with him in having to pay a fine.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 94 largest English towns having an estimated population of 17,559,219 persons in the middle of this year, 8799 births and 7276 deaths were registered during the week ending Feb. 10th. The annual rate of mortality in these towns, which had steadily increased from 14·8 to 18·6 per 1000 in the three preceding weeks, further rose to 21·6 per 1000 in the week under notice. During the first six weeks of the current quarter the mean annual death-rate in these large towns averaged 17·0 per 1000, while in London during the same period the average annual death-rate did not exceed 16·3 per 1000. The annual death-rates last week in the several towns ranged from 10·0 in Stockton-on-Tees, 10·1 in Walthamstow and in Southend-on-Sea, 10·7 in Ilford, 11·9 in Devonport, and 12·1 in Swindon, to 31·5 in Plymouth, 32·1 in Gloucester, 32·8 in Merthyr Tydfil, 34·2 in Aberdare, and 40·4 in Walsall.

The 7276 deaths from all causes in the 94 towns were 998 in excess of the number in the previous week, and included 435 which were referred to the principal epidemic diseases, against numbers rising from 297 to 401 in the three preceding weeks. These 435 deaths from the principal epidemic diseases included 186 from whooping-cough, 98 from measles, 64 from diphtheria, 49 from infantile diarrhœal diseases, 22 from scarlet fever, and 16 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 1·3 per 1000, or 0·3 per 1000 above the average recorded in the five preceding weeks. The deaths attributed to whooping-cough, which had been 81, 94, and 166 in the three preceding weeks, further rose to 186 last week, and caused the highest annual death-rates of 2·4 in Barrow-in-Furness, 2·7 in Preston, 3·7 in St. Helens, 3·9 in Dewsbury, 4·5 in Walsall, and 5·7 in Merthyr Tydfil. The deaths referred to measles, which had been 64, 72, and 63 in the three previous weeks, rose to 98 last week; the highest annual death-rates from this disease were 1·2 in Manchester, 1·4 in Oldham, 1·8 in Newport (Mon.), and 7·1 in Warrington. The fatal cases of diphtheria numbered 64, against 60, 53, and 71 in the three preceding weeks, and included 15 in London and its 14 suburban districts, 4 in Bolton, and 3 each in Norwich, Plymouth, Nottingham, and Preston. The deaths attributed to infantile diarrhœal diseases, which had been 55, 47, and 67 in the three previous weeks, declined to 49 last week; 19 deaths were recorded in London and its suburban districts, 3 in Birmingham, 3 in Liverpool, and 3 in Manchester. The 22 deaths referred to scarlet fever were equal to the average recorded in the three preceding weeks, and included 4 which were registered in Liverpool. The 16 fatal cases of enteric fever, of which 4 occurred in Sheffield, were also equal to the average in the three previous weeks.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had steadily decreased from 2213 to 1500 in the 12 preceding weeks, slightly rose to 1512 on Saturday last; 178 new cases of this disease were admitted to these institutions during the week, against 162, 158, and 169 in the three preceding weeks. These hospitals also contained on Saturday last 1172 cases of diphtheria, 369 of whooping-cough, 137 of measles, 50 of enteric fever, and 2 of small-pox. The 1763 deaths from all causes registered in London were 225 in excess of the number in the previous week, and were equal to an annual death-rate of 20·3 per 1000. The deaths referred to diseases of the respiratory system, which had steadily increased from 290 to 394 in the four preceding weeks, further rose last week to 545, and were no fewer than 141 in excess of the number recorded in the corresponding week of last year.

Of the 7276 deaths in the 94 large towns 222 resulted from different forms of violence, and 541 were the subject of coroners' inquests. The causes of 85, or 1·2 per cent., of the deaths registered in the week under notice were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in London and in 13 of its 14 suburban districts, in Leeds, Bristol, Bradford, Salford, Cardiff, Bolton, and in 44 other smaller towns. The 85 uncertified

causes of death last week included 18 in Birmingham, 17 in Liverpool, 5 in Sunderland, 4 in Nottingham, 4 in Manchester, and 3 each in Stoke-on-Trent, Coventry, Southport, and Darlington.

HEALTH OF SCOTCH TOWNS.

In the 18 largest Scotch towns having an estimated population of 2,182,400 persons in the middle of this year, 1080 births and 953 deaths were registered during the week ending Feb. 10th. The annual rate of mortality in these towns, which had increased from 17·3 to 19·1 in the three preceding weeks, further rose to 22·8 per 1000 in the week under notice. During the first six weeks of the current quarter the mean annual rate of mortality in these Scotch towns averaged 18·8 per 1000, and was 1·8 per 1000 above the mean rate recorded in the 94 large English towns during the same period. The annual death-rates in the several Scotch towns last week ranged from 10·4 in Govan, 11·3 in Motherwell, and 15·3 in Falkirk, to 26·6 in Glasgow, 29·5 in Greenock, and 31·8 in Perth.

The 953 deaths from all causes were 156 in excess of the number in the previous week, and included 100 which were referred to the principal epidemic diseases, against 89 and 100 in the two preceding weeks. Of these 100 deaths, 62 resulted from measles, 14 from whooping-cough, 13 from diphtheria, 6 from infantile diarrhœa, 3 from scarlet fever, and 2 from enteric fever, but not one from small-pox. These 100 deaths from the principal epidemic diseases were equal to an annual death-rate of 2·4 per 1000, or 1·1 per 1000 above that recorded in the 94 large English towns. The deaths attributed to measles, which had been 56, 39, and 55 in the three preceding weeks, further rose to 62 in the week under notice, and included 49 in Glasgow, 7 in Greenock, 2 in Edinburgh, and 2 in Aberdeen. The deaths referred to whooping-cough, which had been 18, 18, and 14 in the three previous weeks, were again 14 last week; and of this number 7 occurred in Glasgow and 3 in Coatbridge. The 13 fatal cases of diphtheria were 1 in excess of the average number in the five preceding weeks, and included 5 in Glasgow and 2 in Aberdeen. The deaths referred to infantile diarrhœal diseases, which had increased from 9 to 13 in the three preceding weeks, declined to 6 last week; 3 deaths were registered in Glasgow. The 3 fatal cases of scarlet fever were 2 fewer than the number in the previous week, and comprised 2 in Aberdeen and 1 in Partick. The 2 deaths attributed to enteric fever were registered in Glasgow and Hamilton respectively.

The deaths referred to diseases of the respiratory system, which had increased from 120 to 144 in the three preceding weeks, further rose to 220 last week; and 22 deaths resulted from different forms of violence.

HEALTH OF IRISH TOWNS.

In the 22 town districts of Ireland, having an estimated population of 1,157,014 persons in the middle of this year, 526 births and 688 deaths were registered during the week ending Feb. 10th. The annual rate of mortality in these towns, which had steadily increased from 18·0 to 24·6 per 1000 in the six preceding weeks, further rose to 31·0 per 1000 in the week under notice. During the first six weeks of the current quarter the mean annual death-rate in these Irish towns averaged 23·1 per 1000; in the 94 large English towns the mean annual death-rate during the same period did not exceed 17·0, while in the 18 Scotch towns it was equal to 18·8 per 1000. The annual death-rates in the several Irish towns last week were equal to 26·6 in Dublin (against 20·3 in London), 41·7 in Belfast, 23·8 in Cork, 20·4 in Londonderry, 17·7 in Limerick, and 20·9 in Waterford; while in the 16 smallest of these Irish towns the death-rate last week was equal to 27·5 per 1000.

The 688 deaths from all causes in the 22 Irish towns were 143 in excess of the number in the previous week, and included 49 which were referred to the principal epidemic diseases, against 30 and 31 in the two preceding weeks; of these 49 deaths, 25 resulted from whooping-cough, 8 from diarrhœal diseases, 6 from diphtheria, 5 from measles, 3 from enteric fever, and 2 from scarlet fever, but not one from small-pox. These 49 deaths from the principal epidemic diseases were equal to an annual death-rate of 2·2 per 1000; the death-rate from these diseases did not exceed 1·3 in the large English towns, while in the Scotch towns it was equal to 2·4 per 1000. The deaths attributed to whooping-cough, which had been 15 in each of the two preceding weeks, rose to 25 last week, and included 15 in Belfast and 5 in Dublin. The deaths referred to diarrhœal diseases, which had been 5 and 7 in the two previous weeks, were 8 last week, all but one of which related to infants under two years of age; 4 deaths were recorded in Dublin and 2 in Kilkenny. The fatal cases of diphtheria, which had been 3 in each of the four preceding weeks, rose to 6 last week, and comprised 3 in Dublin and 3 in Belfast. The 5 deaths attributed to measles were 3 in excess of the number in the previous week, and included 4 recorded in Dublin. The 3 deaths referred to enteric fever occurred in Dublin, Belfast, and Limerick respectively. The 2 fatal cases of scarlet fever, which were registered in Dublin and Galway respectively, were one fewer than the average in the three preceding weeks.

The deaths referred to diseases of the respiratory system, which had steadily increased from 83 to 184 in the seven preceding weeks, further rose to 239 in the week under notice. Of the 688 deaths from all causes in the 22 Irish towns last week, 185, or 27 per cent., occurred in public institutions, and 13 resulted from different forms of violence. The causes of 34, or 4·9 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 94 large English towns the proportion of uncertified causes of death last week did not exceed 1·2 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Fleet-Surgeons: J. McElwee to the *Indomitable*, and for general staff duties on transfer of flag; P. V. Jackson to the *Shannon*, and for general staff duties, on recommissioning; and E. A. Shaw to the *Antrim*, on recommissioning. Staff-Surgeons: A. R. H. Skey to the *Indomitable* on recommissioning, until she becomes flagship of Second Cruiser Squadron; N. H. Harris to the *Indomitable*, on transfer of flag; and E. F. Ellis to the *Shannon*, on recommissioning. Surgeons: G. A. Bradshaw to the *Bramble*, additional, and on recommissioning; and F. W. Quirk to the *Moorhen*.

ROYAL ARMY MEDICAL CORPS.

The undermentioned officers are placed on retired pay:—Lieutenant-Colonel Frederick P. Nichols (dated Feb. 9th, 1912). Major Ernest C. Anderson, D.S.O. (dated Jan. 30th, 1912).

The undermentioned Captains to be Majors (dated Jan. 25th, 1912):—William L. Baker, Frederick W. Cotton, Frank M. Parry, Bertram R. Dennis, William J. P. Adye-Curran, John Powell, William Bennett, Thomas Biggan, Basil S. Bartlett, Dermot O. Hyde, Albert E. Hamerton, D.S.O., George J. Houghton, John G. Churton, Arthur D. Waring, Alfred F. Weston, James Dorgan, Charles H. Furnivall, and FitzGerald G. FitzGerald.

Surgeon-General J. G. MacNeece, C.B., principal medical officer of the Sixth (Poona) Division, Southern Army, India, proceeds home. Colonel F. H. Treherne has taken up duty as Principal Medical Officer of the Bangalore and Southern Brigades at Ootacamund. Lieutenant-Colonel N. C. Ferguson, C.M.G., has taken over charge of the Military Hospital at York. Lieutenant-Colonel G. Cree, medical inspector of recruits in the Eastern Command, has been selected for the increased rate of pay under Article 317 of the Royal Warrant. Lieutenant-Colonel W. Turner has taken up duty in charge of the Connaught Hospital at Aldershot. Lieutenant-Colonel A. L. F. Bate has arrived home from India. Lieutenant-Colonel T. B. Winter has assumed command of No. 9 Company of the Royal Army Medical Corps at Colchester on appointment as Senior Medical Officer. Lieutenant-Colonel W. L. Gray has embarked for a tour of service in India.

Major H. N. Dunn, commanding the Station Hospital at Dagshai, Simla Hills, has been detailed for duty on board the hired transport s.s. *Dongola*, leaving Bombay for Southampton on Feb. 23rd. Major H. G. F. Stallard has been

transferred from Cherat to Peshawar. Major E P. Connolly has taken up duty with the Third (Lahore) Division of the Northern Army in India. Major A. W. Bewley has been transferred from Landour cantonment to Meerut. Major H. S. Taylor has been appointed to the Scottish Command. Major E. M. Morphew has taken up duty at Preston. Major F. J. W. Porter, D.S.O., has been transferred from Reading to the Military Hospital at Cosham. Major P. H. Collingwood has taken up duty at Plymouth. Major A. C. Fox has arrived home for duty from Hong-Kong. Major J. W. West has been appointed to Rawal Pindi. Major W. G. Beyts has been transferred from Ranikhet to command the Station Hospital at Roorkee.

Captain J. Tobin has been ordered to join at Gibraltar. Captain J. J. O'Keefe has been granted eight months' general leave of absence home from India. Captain W. J. Waters has joined for duty at Tientsin. Captain H. F. Shea has been appointed Surgical Specialist at the Station Hospital, Ambala. Captain F. A. Stephens has embarked for a tour of service in India. Captain J. S. Bostock has joined for duty at Delhi. Captain W. Davis has been transferred from Bareilly to the Station Hospital at Meerut. Captain W. J. S. Harvey has arrived in Jamaica for a tour of foreign service. Captain M. B. H. Ritchie has arrived home on leave of absence from India. Captain F. C. Lambert has been appointed to Preston for duty. Captain A. H. C. Gray has been selected for attachment to the Dublin University Contingent of the Senior Division, Officers Training Corps. Captain J. B. Meldon has been posted to the Military Hospital at Dover. Captain E. M. Glanvill has been transferred from Leeds to Newcastle. Captain H. Harding has taken up duty at York. Captain B. A. Craig has been appointed to the Royal Army Medical Corps Depôt at Aldershot for a course of instruction. Captain J. H. Campbell has joined for duty at Newport.

The following lieutenants have been appointed for duty: H. G. Monteith, D. W. Bruce, L. Buckley, A. G. J. MacIlwaine, and I. R. Hudleston to the Aldershot Command; and B. H. H. Spence, S. P. Sykes, E. J. H. Cowen, W. Stewart, and R. Davidson to the Eastern Command. Lieutenant D. H. C. MacArthur has been transferred from Dagshai to Ambala. Lieutenant C. H. O'Rorke has taken up duty at the Station Hospital, Bareilly. Lieutenant R. G. M. Kinkhead has been appointed to the Military Hospital at Queenstown. Lieutenant J. Gilmour has embarked for service in Egypt. Lieutenant P. M. J. Brett has been transferred from the Royal Victoria Hospital, Netley, to Cosham. Lieutenant M. White, on arrival in India, has been posted to Lucknow to undergo a course of instruction in military sanitation.

INDIAN MEDICAL SERVICE.

Colonel T. Grainger, C.B., has been selected for appointment as Principal Medical Officer of the Fifth (Mhow) Division, in succession to Colonel C. F. Willis, C.B. Lieutenant-Colonel A. W. Dawson has taken over civil medical charge of Roorkee in addition to his military duties, vice Captain J. J. O'Keefe, R.A.M.C.

Major E. F. G. Tucker has been appointed to officiate as Presidency Surgeon, Third District, and in medical charge of the Common Prison, House of Correction and Byculla Schools, Bombay, vice Major A. W. Tuke. The services of Major H. D. Peile, Superintendent of the Central Prison in the United Provinces of Oudh and Rohilkhand, have been placed at the disposal of the Home Department of the Government of India. Major R. H. Elliot has returned to India from leave of absence home. Major J. H. McDonald has been appointed Civil Surgeon at Surat, vice Major C. C. Murison transferred. Major J. W. Cornwall has been granted two years' furlough home from India.

The services of Captain J. E. Clements have been placed at the disposal of the Government of the United Provinces for employment in the Jail Department. Captain D. M. C. Church has been granted one year's leave of absence home from India. Captain V. B. Nesfield, officiating deputy sanitary commissioner, has been appointed to act as Civil Surgeon at Bijnor. The services of Captain S. B. Mehta have been replaced at the disposal of His Excellency the Commander-in-Chief. Captain R. B. Nicholson has been granted leave of absence for one year. Captain H. S. Hutchison has been appointed to officiate as Deputy Sanitary Commissioner for the Sind Registration District. Captain N. S. Wells has been granted one month's extension of his leave of absence home on the recommendation of a medical board. Captain W. P. G. Williams has been appointed to officiate as Superintendent of the Central Jail at Cannanore, Madras Presidency. Captain B. B. Paymaster has been granted two years' furlough. Captain R. E. Lloyd, professor of biology at the Medical College, Calcutta, has been granted two years' furlough home. Captain W. J. Frazer has been transferred from Chanda to Dehra Dun for a course of instruction at the X Ray Institute. Captain F. T. Thomson has been granted six months' leave of absence on the recommendation of a medical board. Captain J. B. Christian has been appointed Civil Surgeon at Tippera. Captain J. M. A. Macmillan has taken up duty at Hoshangabad as Civil Surgeon. Captain R. E. Wright has been appointed to officiate in the Bacteriological Department, and his services have been placed at the disposal of the Government of Madras. Captain A. G. McKendrick has taken up duty as Statistical Officer to the Government of India in the Sanitary and Medical Departments during the absence of Major S. P. James on deputation to visit the Panama Canal Zone and to attend the Far East Tropical Medical Association.

Lieutenant F. J. Kolaporewalla has been appointed a Specialist in the Prevention of Disease and placed in charge of the Bacteriological Research Laboratory at Rangoon. Lieutenant P. Connellan has been placed under orders to embark for India.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Lieutenant Charles W. C. Myles is seconded for service with the Dublin University Contingent, Officers Training Corps (dated Feb. 10th, 1912).

No. 18 Field Ambulance: Lieutenant Thomas Carnwath resigns his commission (dated Feb. 10th, 1912).

Correspondence.

"Audi alteram partem."

KING EDWARD'S HOSPITAL FUND FOR LONDON AND THE EVELINA HOSPITAL.

To the Editor of THE LANCET.

SIR,—We venture to trouble you with the following observations in order to remove a misapprehension as to the attitude of King Edward's Hospital Fund which may arise from the published letter of the chairman of the Evelina Hospital. In his statement of the reasons for the refusal of a grant by the King's Fund, the chairman presents the necessary result of a deliberate act of his committee as if it were the arbitrary act of the Fund; he has omitted to mention that in the Fund's official notification of the reasons why no grant could be made it was stated that "no application could be considered until *the regulations of the Revised Uniform System of Hospital Accounts were complied with by* the replacement of the sum of £3620 transferred from the General Fund to the Samaritan Fund."

The Revised Uniform System of Hospital Accounts was adopted in 1906 by the King's Fund, the Hospital Sunday Fund, and the Hospital Saturday Fund, with the concurrence of a representative committee of hospital secretaries in order to enable the yearly financial operations of the various London hospitals to be correctly compared. In fairness both to the hospitals generally and to the subscribing public the King's Fund is bound to see that the system is observed by institutions applying for grants.

The regulation which the Evelina committee have ignored is one not of form but of substance, and the effect on the accounts is important. A sum of £3620, which they have full power to apply to the general purposes of the hospital, particularly to meet a deficit in working, is shown on their balance-sheet under the heading specially reserved for funds which cannot be applied to meet a deficit in working or other general purposes. Similarly the income from this considerable sum is excluded from the income and expenditure account.

If, therefore, these accounts are published as being in accordance with the Revised Uniform System, the balance

sheet is to this extent incorrect and the income and expenditure account is incomplete; if these accounts are not intended to be interpreted according to the Uniform System, then the hospital committee are confessedly not observing the system and are making the hospital ineligible for a grant. There is thus nothing arbitrary in the King's Fund action; it is the automatic result of the free choice by the hospital committee of a course which inevitably produces this dilemma.

The Fund appreciates the courteous terms in which the chairman of the hospital refers to its previous relations with the Fund, but we must point out that the Fund has not interfered with the management of the hospital. The customary stipulation that there should be an inquiry officer can hardly be so described, and if it could it is not the point at issue. Even with regard to the method of publishing the accounts, the Fund is only concerned because the receipt of a grant would imply that the accounts were in the recognised form which enables the financial position and operations of one hospital to be compared with those of other hospitals. Unfortunately the accounts of the Evelina Hospital are not in this form.

We are, Sir, your obedient servants,

SAVILE CROSSLEY, JOHN G. GRIFFITHS, } Honorary Secretaries.

7, Walbrook, London, E.C., Feb. 8th, 1912.

M. BERGSON'S "CREATIVE EVOLUTION."

To the Editor of THE LANCET.

SIR,—Dr. R. F. Licorish has referred to me in his letter in THE LANCET of Feb. 10th on the above work, and I should like to be allowed to add a few observations. M. Bergson is not the first to deal with what I would call the "New Teleology." The first to raise the question of a "determining" power was James Croll in his essay, "What Determines Molecular Motion?—The Fundamental Problem of Life."[1] Darwin left it unanswered, but while his theory of natural selection only *assumes* the possibility of adaptive variations arising, what *causes* them is not suggested, beyond recognising some "direct action" of a changed environment. However, he more than once attributes them to the Creator.[2] Since, however, the existence of adaptive variations is (as he says) a mere "accident,"[3] there being no natural law of cause and effect to account for adaptations or uses, Haeckel was justified in saying, "Darwin gave us the clue to the monistic explanation of organisation,"[4] for any *directed* adaptation is incompatible with a non-directed accident.

As far as I know, the next attempt was in an article of my own on "Directivity" in the *Hibbert Journal*.[5] This word was coined by the eminent chemist, Sir H. H. Church, upwards of half a century ago. He told me that he felt the want of a word to express the fact that as he could "direct" various inorganic substances in his laboratory, with which, by synthetic processes, he could produce certain so-called organic compounds as madder, indigo, certain sugars, urea, &c., what is it in plants and animals which can do the same thing as himself? So he invented the word "directivity."

Directivity, however, covers a much wider ground than organic products, for it applies to the *making of any and every structure* which has some definite purpose in view. In other words, it lies at the basis of evolution. Scientists limit themselves to all phenomena which come under the possibilities of inorganic matter and force. What transcends their activities falls under philosophy and natural theology. Directivity stands on the borderland of both, as being a purely abstract term. But if we ask what or who directs? the only scientific answer is "Life."

The activities of life are observable, just as those of electricity, heat, magnetism, and other forces are; but we know no more of the *nature* of *force* than we do that of *life*. Dr. A. Russel Wallace in his latest work, "The World of Life, a Manifestation of Creative Power, Directive Minds, and Ultimate Purpose," would endeavour to combine "directivity" with, or as an "extension" of, natural selection; but, they are, in fact, mutually exclusive. He is right, however, when he says: "What we must assume is not merely a force, but some agency which can and does apply, direct, guide, and coördinate a great variety of forces ..... so as to build up that infinitely complex machine, the living organism, which is not only self-repairing but self-renewing, self-multiplying, *self-adapting to its ever-changing environment.*" These words which I have italicised remind me of the title to one of my volumes of the International Scientific Series—viz., "The Origin of Plant Structures by Self-adaptation to the Environment" (1895). Protoplasm has been called "Purposive Matter" as the cause of adaptations; but matter, being inert and lifeless, is powerless to do anything. It is the life infused in protoplasm which is the active agent throughout all the activities of organic beings. Similarly, the old term "Vital Force" is a misnomer, for no force is alive; but it is *Life* which *directs forces* to *move matter*, so that a purposeful, concrete, organic structure is the result.

The conclusion, therefore, is that directivity resides in life alone, and not in any force or kind of matter itself. Beyond that science cannot advance; but philosophy or natural theology takes up the question and returns to Paley, but with a change of the title. "Argument of Design" becomes "Self-adaptation" by response to changed conditions of the environment; the result is evolution under the directivity of life.

I am, Sir, yours faithfully,

Bournemouth, Feb. 11th, 1912. GEORGE HENSLOW.

To the Editor of THE LANCET.

SIR,—Dr. R. F. Licorish, in THE LANCET of Feb. 10th, advances what professes to be an interpretration of Bergson's philosophy. His main point is that Bergson agrees with the Neo-Lamarckians in believing in the inheritance of acquired characters. Bergson condemns the Neo-Darwinian theory as being an inadequate explanation of evolution, but the one point on which he agrees with the Neo-Darwinian is that a tendency to the inheritance of acquired characters, if it ever occurs, can occur but rarely. This is one of the most definitely expressed opinions in his "Évolution Créatrice."

I disagree absolutely with Bergson's theory, but this is no reason for allowing a serious misrepresentation of it to pass unnoticed. Fundamentally Bergson's idea of the universe is no more than a modernised version of Paley's "Evidences." It is perfectly obvious that the most modern of the most modern branches of science fail to explain many important phenomena, among them the origin of life and consequently of man's intellectual capacities. Failing the explanation of such phenomena, Bergson, following in the footsteps of many others of at least equal reputation, assumes the existence of a metaphysical power which has directed and continues to direct evolution. Whether, in the absence of physical evidence with regard to the cause of a phenomenon, it is justifiable to assume the existence of a power beyond our understanding and incapable of proof, must remain a matter for each to decide for himself. Personally, I prefer to wait with an open mind in the hope that some further evidence may be forthcoming.

The fact that has struck me most forcibly in Bergson's writings is his total misunderstanding of the theory of evolution by natural selection. His misrepresentation of the belief of the Neo-Darwinian is almost as grotesque as that of the Neo-Lamarckian. And the curious thing is, that one of the most important *raisons d'êtres* of his theory as propounded by himself is that the Neo-Darwinian theory is inadequate.

I am, Sir, yours faithfully,

Glasgow, Feb. 11th, 1912. CHARLES WALKER.

THE FATE OF THE APPENDIX AFTER ABSCESS FORMATION.

To the Editor of THE LANCET.

SIR,—I can fully endorse many of the points which Mr. Dodds-Parker has emphasised in his interesting and valuable contribution to the surgery of the appendix. That it is not only desirable but essential for the safety of the patient to perform a secondary operation for the removal of the appendix after it has been the seat of suppuration there can be no doubt whatever; it is a damaged organ and is therefore liable to be the cause of further trouble. I have often seen it distorted in outline, kinked, or bound down by

[1] Phil. Mag., July, 1872.
[2] See Origin, &c., the last sentence.
[3] An. and Pits., under Dom., ii., p. 431.
[4] Riddle, &c., 264, 5.
[5] Vol. vi., p. 159.

adhesions, and I have also seen the distal part almost separated except for a band of cicatricial tissue. At the same time I suppose every surgeon can recall cases in which there has been no more trouble after an appendix abscess after the lapse of years, and where the patient was willing to run the risk rather than undergo a secondary operation; although this may occasionally happen it is well recognised that further trouble is by no means infrequent.

I should also like to refer to the frequency of ventral hernia in children after appendix abscess; I believe it is of more frequent occurrence than in the adult. I quite agree with Mr. Dodds-Parker that the rectus incision is the best for interval operations, but where a ventral hernia or a weak scar exists I excise the scar and utilise the incision for the removal of the appendix and restoration of the abdominal wall.

I have often been struck by the almost complete absence of adhesions after an appendix abscess, nothing but a few web-like threads are sometimes met with except just around the appendix itself, which may be bound down by adhesions to the cæcum and surrounding structures.

I am, Sir, yours faithfully,

Wimpole-street, W., Feb. 14th, 1912. DOUGLAS DREW.

To the Editor of THE LANCET.

SIR,—I was much interested in Mr. A. P. Dodds-Parker's paper, read before the Oxford Medical Society on Dec. 8th, 1911, and published in your columns last week. For the past eight years it has been my practice to remove the appendix after every case of abscess formation as soon as the resulting sinus has healed (if I could obtain permission to do so). My experience with regard to hospital and private patients has been different from Mr. Dodds-Parker; that in the last eight years of hospital practice I have only had one patient who refused to be operated on after the abscess had healed, and, curiously enough, this patient returned one year later under my care with an acute attack of perforative appendicitis, so I was able to remove his appendix at the operation, whereas in private practice I have only been able to get permission in a few cases to remove the appendix after abscess formation, owing in most cases to the popular idea that the appendix is destroyed in such cases. My operative experience in the past eight years of removal of the appendix after abscess formation is 34 cases. In all these cases the appendix has been found and removed, and in all it could be clearly demonstrated that the appendix was not destroyed, the perforation had healed, and that the lumen was patent to a greater or lesser extent. Many contained concretions, and several were examined pathologically, and I firmly believe that every one of these appendices was capable of taking part in another attack of acute appendicitis. It was interesting to note that in two of my cases the appendices had been separated from the cæcum, and that the separated base had got attached to parietal peritoneum in the iliac fossa, the lumen was patent in both, and both contained concretions. And that such a separated appendix was capable of producing an acute attack of appendicitis I was able to prove a few weeks ago when I was asked to operate on a little boy 36 hours after the commencement of an acute attack. This patient had had a severe attack a year and a half previously but was not operated on. I found the appendix lying under the cæcum, its tip was attached to the mesentery of the small intestine, and its base was adherent to a mass of adhesions adherent to the peritoneum in the iliac fossa. Having separated this end I found it was a blind end also, there was a concretion in the middle and a perforation by the side of it. The pelvis was full of muco-pus. I could clearly demonstrate the healed stump of the appendix on the cæcum. Drainage tubes were used, there was no sign of a fæcal fistula, and the wound healed in three weeks.

In conclusion, I should like to add that in THE LANCET of Oct. 1st, 1904, having operated on several of these cases, I published a case under the heading of "An Unusual Case of Suppurative Appendicitis." I published this case chiefly for the reason that Mr. (now Sir) Anthony Bowlby, in a clinical lecture published in THE LANCET of July 9th, 1904, p. 61, on these cases, stated that "suppuration destroyed the appendix." In my remarks on the case that I published I then stated that removal of the appendix after the occurrence of an abscess seems to me to be just as important as removal of the appendix after an attack of non-suppurative appendicitis, and from further experience I am convinced that the appendix should always be removed after abscess formation, but if every case of appendicitis was operated on within the first 48 hours there would be no need to study the condition of the appendix after abscess formation!

I am, Sir, yours faithfully,

H. J. GODWIN,
Hon. Surgeon to the Royal Hampshire County
Winchester, Feb. 12th, 1912. Hospital, Winchester.

DIABETIC GANGRENE.

To the Editor of THE LANCET.

SIR,—Mr. Lockwood, in his clinical lecture on Amputation for Diabetic Gangrene,[1] after a very complimentary reference to my book on "Physiological Principles in Treatment," goes on to say, "And yet it seems strange to me that at the end of that chapter (on Diabetes and Acidosis) he does not say, 'Therefore you must give these patients as much oxygen as you can get them to take.'" He has apparently overlooked the fact that on p. 232 (second edition) I say, "In a condition which ..... we believe to be associated with deficient oxidation, to which the characteristic air-hunger also points, inhalations of oxygen may reasonably be tried." I go on to point out that as in acid intoxications the cell lacks oxygen because a link is missing, not much can be expected from such inhalations. Just in the same way the cell needs dextrose, but in severe diabetes is unable to utilise it. We need nitrogen in our food but cannot use the nitrogen of the air for this purpose. Mr. Lockwood has seen great benefit from oxygen inhalations in his operation cases of diabetic gangrene. I would suggest that this was because of their stimulating effect on the heart, for he notes that before administration there was marked cyanosis and the exuded blood was very dark. Such cyanosis is very unusual in uncomplicated diabetic coma, and even at the necropsy the blood is brighter than usual, presumably because of the defective interchange between the blood and the tissues. I think, therefore, that we are talking of rather different conditions. I am, Sir, yours faithfully,

Welbeck-street, W. W. LANGDON BROWN.

THE ADMISSION OF VENEREAL CASES TO GENERAL HOSPITALS.

To the Editor of THE LANCET.

SIR,—If your correspondent had read my letter more carefully she would have seen that I expressed no opinion whatever either for or against the admission of venereal cases to general hospitals, and certainly urged no plea, valid or otherwise, against the provision of special accommodation for them. On the contrary, I took their admission for granted, and urged that in addition to the special wards and special training for the medical men in charge of them, advocated by Dr. Douglas White and Lieutenant-Colonel Melville, there should be a special staff of trained women to nurse them. Surely "Charity's mantle" can be worn by experienced women as well as by young girls in training; and have young probationers no "claim on our human sympathies" so that we matrons may protest against their being compulsorily employed in a special class of nursing for which neither their age nor experience fits them?

I am, Sir, yours faithfully,

Feb. 13th, 1912. A HOSPITAL MATRON.

GUARDIANS AND DISSECTION.

To the Editor of THE LANCET.

SIR,—The letter which you published last week from Mr. F. G. Parsons with reference to the refusal by the Southwark board of guardians to permit unclaimed bodies under their control to be used for dissection reveals a very serious state of affairs. All medical men must agree with Mr. Parsons's fair and logical statement of the case for the schools

[1] THE LANCET, Feb. 10th, 1912, p. 349.

of anatomy, and I hope that you, Sir, will endorse his appeal for a campaign of public enlightenment.

I am, Sir, yours faithfully,

Feb. 13th, 1912. M.D.

*** We intend to deal with the subject of Mr. Parsons's letter in an early issue of THE LANCET.—ED. L.

THE MEDICAL PROFESSION AND THE NATIONAL INSURANCE ACT.

To the Editor of THE LANCET.

SIR,—In a recent article on the National Insurance Act, you remarked that the profession would now welcome the intervention of the great medical corporations as guides to a constructive policy. Nothing, I believe, of more fundamental importance could be said. I am no longer on the Council of the Royal College of Surgeons of England and I have no information as to what course it and the Royal College of Physicians of London are taking. The services which the Colleges, I have no doubt, are prepared to render alike to the public, the Government, and the profession, cannot be obtained from any other source, and they may well be the turning point in the construction of a position which can be accepted as sound and equitable. The vital interests of the community and the profession are beyond doubt very gravely involved as matters stand. Had the whole question been made the subject of a conference between the Government and the two Colleges before the Bill was framed the present deadlock might have been avoided, because the real facts of the case would have been brought to light. I can remember instances when I was on the Council in which the Government consulted the Colleges and in which those bodies were able to render material assistance. I remember, also, the generous terms in which these services were acknowledged by the Government of the day.

I am, Sir, yours faithfully,

Cambridge. HOWARD MARSH.

To the Editor of THE LANCET.

SIR,—Will you allow me to put before you and your readers some arguments why, even though the Insurance Act has been passed, it should not without considerable amendment be put into practice. Without consulting those who have considered, and under all sorts of difficulties and largely at their own expense have dealt with, the sickness in the land, Mr. Lloyd George and the House of Commons settled down to discuss details; they did not trouble to think of the principles which should underlie the Act.

One acquainted with the traditions of Dartmoor is irresistibly reminded of

> "Lidford Law,
> Where in the morn they hang and draw
> And sit in Judgment after."

Though the Act is passed it is not irrevocable, and we medical men have an idea that even the Government, though they forced the Bill through Parliament and have presented it to a country which looks askance at the gift, are now, though late in the day, not disinclined to "sit in judgment after."

In the minds of the advocates of the Act there is a conception of the origin and treatment of disease which is erroneous. It is supposed that if a man or woman is not deterred by pecuniary considerations from consulting a doctor disease will be aborted or arrested; in other words, it is supposed that chronic disease leading to disablement comes from the neglect of some definite condition. It would be easy to demonstrate, whether in the out-patient rooms of any large hospital, or in the dispensary of a doctor in the East of London, or in the consulting-room of the West-End physician, that, except in cases of infection and injury, most of the diseases, preferably described as morbid conditions, which lead to total or partial disablement from work, do not come on suddenly and definitely, but slowly and insidiously, and that they depend on faulty hygiene and faulty habits. The only cure for them is prevention, and the only way to prevent them is through the education of the patient by the doctor.

From personal experience as a general practitioner for 18 years, and subsequent special practice, and from remarks made to me by not a few other doctors, I know that the general practitioner and the hospital physician alike are at present unable to devote the necessary time to the instruction of the patient. And everyone who knows anything of general medical practice is convinced that under the Insurance Act there must be a great augmentation of the work of the already greatly overworked general practitioner. Of course, there are doctors with plenty of spare time, but the public have decided that their services are not worth seeking. Now in the vast majority of cases, what a patient, especially an ignorant and unintelligent patient, asks a doctor is not "What can I do to get quite well?" but "What can you give me to ease my present pain or discomfort?" So that under the new Act, with an increased number of cases to attend to, the doctor will have even less time and opportunity than he has now to teach his patients rationally, and with a view to permanent amelioration; and sickness, leading to disability, will not be lessened.

If you had space I would ask you to print an extract from Sir F. Treves's work, "The Other Side of the Lantern," where he shows that the exceptionally low mortality of the Japanese in their war with Russia was due to their realising that the only proper cure of disease on a large scale is its prevention. What is true of the treatment of disease in an army is true of the treatment of disease in a nation. From this point of view another very serious defect or omission in the Act is the failure to provide for any proper dental service. I think it was Napoleon who said that "an army marches on its belly." What is true of an army of soldiers is true of an army of workers, and it would be right to say that a "nation works on its belly." It would be easy to demonstrate in the out-patient rooms of any hospital that one large factor, possibly the largest factor, in the causation of chronic disease depends on some morbid condition of the alimentary canal; another indication of this fact might be found in the numerous advertisements of pills and patent medicines which disfigure our landscapes and provide a large revenue for our daily and weekly journals. It is becoming more and more recognised that to prevent these conditions a clean mouth and sufficient teeth to masticate properly are essential. At the present time the vast majority of labourers have defective teeth and unclean mouths.

Dr. Harry Campbell writes in the *British Medical Journal* of Jan. 27th, 1912, "I estimate that among the inhabitants of these islands there are upwards of 200,000,000 carious teeth, and as many alveolar abscesses," and as regards the teeth, I do not think his estimate is too large. In 1000 well-to-do patients seen consecutively I found that nearly 40 per cent. had markedly defective teeth, and over 20 per cent. had septic mouths. Seeing that in all these cases food is improperly masticated, and in septic cases is actually poisoned before it is swallowed, until this condition of affairs is altered a really high standard of health is impossible, and to attempt to improve the health of the labouring class to any great extent without providing for adequate dental service is more foolish than to try to make bricks without straw; it is to attempt impossibilities.

There is a third point that I should like to put before your readers. It has been enacted that for some fixed pecuniary consideration the services of a large number of medical men are to be at the call of one-third to one-half of the inhabitants of the British Isles, whenever the latter may choose to demand them. Now it does not seem to have occurred to many that to this idea of compulsory medical service there is a definite corollary—viz., that the patient should be under some compulsion to carry out the doctor's orders. The public must get rid of the idea that when a man is sick his recovery depends on his taking some medicine or other; it depends infinitely more on what he himself does or refrains from doing. "Don't rely on the medicine I prescribe, but do what I tell you," is very often, with intelligent medical men, the parting injunction to their patients. At present, assuming a patient does not follow the doctor's advice and returns time after time with the same complaint he has at any rate to pay the doctor a fee for each unnecessary quarter of an hour he takes up. But in future he can return and waste the doctor's time as often as he likes. In the military and naval services and in the workhouse infirmaries where there is contract medical service, and in the wards of general hospitals, where gratuitous relief is given by many of the ablest medical

men, the patient *has* to do as he is told. At present in club practice the patients are the more intelligent and thrifty of their class, and as it is their own money that is being spent when they are on the sick list there are inducements for them to take the doctor's advice. But in future the less intelligent and less thrifty are to be entitled to free medical treatment, and with no compulsion or even inducement to follow the doctor's advice.

Let me give a case to illustrate my point. The patient is a man, aged 35, a mechanic. During the last five years he has frequently been incapacitated for work owing to what has been called a weak heart. His real trouble is flatulent distension of the stomach, causing pressure on the heart. This is caused: (1) by defective teeth; (2) bolting his food; and (3) unsuitable food. He will not have his teeth attended to, and will not correct his habits. He spends at least £10 a year on doctors and patent medicines. Why should any doctor be compelled—as under the Insurance Act he will be—to attend this man, whether it be at 6*s*. or 10*s*. per annum, if, and as long as, he refuses to take advice and acquire habits which alone could cure him? If this man chooses to play the fool, why should it be at other men's expense? Can anyone imagine a solicitor agreeing—still less can anyone imagine a solicitor being compelled—to give advice at so much a year to all and sundry and to be compelled to devote time to getting them out of difficulties they had got into by not following the first advice he gave them? From Mr. Lloyd George upwards and downwards lawyers would say it would be preposterous to suppose they would undertake such work—at contract rate.

Is it too late to suggest to the members of the Government that now that they realise as they never did before the difficulties that surround national sickness insurance and the *prevention* of national sickness, they should act as statesmen and not as mere politicians? That they should bring in a Bill to suspend the operation of this Act for at least two years (such a Bill would be welcomed by practically all the Members of the House), and that the Commissioners selected to administer the Act, with or without additional members, should be appointed a Commission to inquire into, and report on, the best method of providing for the prevention and treatment of sickness among the working classes, and for the maintenance of the worker during periods of ill-health. If this were done, and took two years to do, the time would be well spent in preparing an edifice to be built on rock in the place of one which has its foundations in the shifting sands and that already is in need of reconstruction before ever it has been put to use.

I am, Sir, yours faithfully,

Llandrindod Wells, Feb. 10th, 1912. R. ACKERLEY.

PS.—The foregoing letter has dealt with illness from the medical side only. It ought to be realised by the Chancellor and the public that hitherto the greater part of the major surgical work for the industrial classes has been done without the least cost to the patient and without the surgeon receiving any remuneration. If an attempt is made to bring the Insurance Act as passed into practice, it is conceivable that surgeons will not continue to do all this gratuitous work; and can any lawyer tell us why they should?

To the Editor of THE LANCET.

SIR,—I agree that an unsuccessful strike would be dreadful, in the loss of prestige. But there is some reason for disagreeing with the conclusion that a successful strike would be deplorable in its public effects, as you suggest in your leading article of Feb. 3rd. There is no necessity to base our refusal to accept the terms of Mr. Lloyd George on pecuniary considerations, but there is every reason for basing such refusal on the ground of belief that the acceptance of the present proposals will be a matter involving great disaster to the cause of progress in the science of medicine and surgery, and consequently a detriment to the public health of this country.

I cannot recollect on any previous occasion when politicians have devised instruments for damaging the interests of medical science that the Royal Colleges of Surgeons and Physicians have taken up a proper position. On this occasion—too tardily, it must be admitted—both of the Royal corporations have made pronouncements, upon which they may be congratulated, and it is much to be desired that these corporations will receive loyal support. I observe that the Chancellor had stated that his Commissioners are, from A to Z, no political partisans. Well, that is possibly true so far as the official parties are concerned, but the question arises as to past and present membership of, say, the Fabian Society or the Social Democratic party. So far as my observation serves me, the principles of State interference with personal freedom are permeating every class in this country, and it is quite patent that the past action of the British Medical Association has been much influenced by the supporters of these principles. The time has indeed now arrived when the enemy should be labelled, and that the two political parties should be frankly—Socialist and Anti-Socialist. As matters now stand, it is always possible to deny political partisanship, because Socialism is not reckoned as being the serious political factor it undoubtedly is.

The conclusion at which I have arrived is that the safest course for the medical profession is to refuse to be drawn into more conferences, official or unofficial, or more political breakfast parties, but to await the time when the Commissioners put their cards on the table, and to recollect that the profession holds an overwhelming hand in trump cards.

I am, Sir, yours faithfully,

Hatfield, Feb. 6th, 1912. LOVELL DRAGE.

To the Editor of THE LANCET.

SIR,—Our system of club practice may not be perfect, but the National Insurance Act seems to me to make it infinitely worse for all except highly paid officials. The present proposals would not affect many of us in the least; hence I write from a purely disinterested point of view. On conversation with a highly trained workman I find that he is perfectly satisfied with the present arrangement, but bitterly resents being put on a level with the thriftless. Whatever solution is reached for the problem, let us secure that our leaders recognise that the *six points* are only the *irreducible minimum*. Like many others, I regard my guarantee to a defence fund solely conditional on the reconstitution of the British Medical Association and their adoption of the six points as their platform.

I am, Sir, yours faithfully,

Feb. 10th, 1912. JOHN CROPPER, M.D. Cantab.

To the Editor of THE LANCET.

SIR,—During the past week many letters, hostile to the medical profession, have appeared in some of the lay newspapers, and their general tenor is to the effect that the medical profession will find that the Act includes their "six points." The following references will show clearly that this is not the case.

1. Under Section 15 (3) the regulations which the Insurance Commissioners are bound to make do no more than authorise the Insurance Committees to require any persons whose incomes exceed a limit to be fixed by the Committees, and to allow any other persons ..... to make their own arrangements, &c. This authorising and this allowing do not involve any compulsion, and *pro tanto* (to say nothing of the composition of the Insurance Committees) the "first point" remains unsatisfied.

2. Section 15 (2) (*c*) allows the insured person to select the doctor, and the doctor to decline the assured person, but this has to be read (1) along with (*d*); and the very probable cases of each one of the doctors declining to attend certain assured persons have still to be provided for; and (2) along with Section 15 (4), which deals with persons (i.e., all present and future members of societies) entitled to receive medical attendance, &c., under any system ..... existing at the time of the passing of the Act; and it says that the regulations shall provide that, in the case of these persons, the "medical attendance, &c., may be treated as ..... and may provide for the Committee contributing," &c. There is no compulsion on the Committee, and, even if there were, the "persons" would be enticed to "select" the "club doctor," to whom this Subsection (4) gives no right to decline to attend the "persons."

3. By Section 14 (1) medical benefits, it is true, are to be administered by and through the Insurance Committees, but seeing that three-fifths of these Committees stand for the insured persons, while only one-fifteenth or one-twelfth or so, according to the size of the Committees, are allowed to the doctors, it is idle to say that the medical benefits are

not administered by the societies, and the same with respect to the maternity benefit, which, in the case of members of a society, is to be administered actually by the society itself.

4 and 5. Section 15 (1) opens the door to "bargaining" (for payments) by doctors with the representatives of the societies, and this is just the indignity to which, I apprehend, the medical profession declines to subject itself. (Fancy solicitors or members of my own profession being called upon to submit to such conditions!) Again, the possible Medical Committees contemplated by Section 62, which are to be "recognised" (!) and "consulted" by the Insurance Committees, are not likely to be able to prevent or remove difficulties, seeing that there is no suggestion that the Insurance Committees are to act upon any advice or recommendation tendered by the Medical Committees.

6. The fact that self-respecting medical bodies have declined, this month, to take part in an *in camerâ* "talk" affords no explanation of the "inadequate" representation of the medical profession on the Commission and on the Insurance Committees which is arranged for in the Act.

Suppose the whole medical profession were to stand aside, how would the Act be "worked"?

I am, Sir, yours faithfully,

Lincoln's Inn, W.C., Feb. 12th, 1912. BERNARD O'CONNOR.

To the Editor of THE LANCET.

SIR,—Will you allow me to ask a few questions concerning the Insurance Act? I believe 6*s.* per head are allotted to medical aid per annum. Now, how much is going to the chemist and how much to the general practitioner? I am told it will not be possible to supply medicine at less than 2*s.* 6*d.* a year, which will only leave the general practitioner 3*s.* 6*d.*

But it will be necessary to have a schedule of drugs to be kept by the dispenser; these drugs must be up to standard. In order to ensure this, periodical testing of the drugs will be required, as in Germany; a staff of analysts must be maintained for the purpose; so that they may be above temptation, they must be well paid. Out of which fund is the money to come?—I am, Sir, yours faithfully,

J. E. FORSTER, M.D. Leipsic.

Brockley-road, S.E., Feb. 6th, 1912.

To the Editor of THE LANCET.

SIR,—I have read with interest the tabulated list of clauses in the Act as affecting the medical profession supplied to you by a correspondent, who, it is stated, has been officially engaged in working upon the Act. The list is published on p. 404 of your issue of Feb. 10th. Why is Section 63 omitted? In none of all the numerous letters appearing in your columns has this section been adequately discussed. Section 63, in my opinion, is one of the fundamental clauses of the Act. In its far-reaching subsections are provisions which will influence for good the homes and environment of generations yet to come.

If Mr. Lloyd George had done nothing more to stamp him as a strong man, Section 63 of this Act would be enough do so. I am, Sir, yours faithfully,

A. B. DUNNE, M.B. Cantab., D.P.H.

Doncaster, Feb. 9th, 1912.

*** Section 63 deals with excessive sickness and inquiries into its cause.—ED. L.

ASSOCIATION FOR PROMOTING THE TRAINING AND SUPPLY OF MIDWIVES.—The eighth annual meeting of this association will be held at Caxton Hall, Westminster, on Thursday, Feb. 29th, at 3.30 P.M. The chair will be taken by Mr. H. Cosmo O. Bonsor, and among the speakers will be Mr. F. E. Fremantle, medical officer of health of Herts.

COLONIAL MEDICAL SERVICES.—*West African Medical Staff:* The following have been selected for appointment to the staff:—Dr. B. A. Percival, Dr. J. W. Thomson, and Mr. R. Willan (Northern Nigeria); Mr. E. J. J. Quirk (Southern Nigeria); and Dr. E. J. Powell (Sierra Leone). *Other Colonies:* Dr. D. C. Robertson has been selected for appointment as a medical officer (Grade III) in the Federated Malay States.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Annual Report of the Royal Infirmary.

THE report just issued states that steps have been taken to purchase a site in the city for the purposes of a central branch, which, with the buildings to be erected on it, is to cost £45,000. A considerable part of the report deals with the Insurance Act. There seems to be a consensus of opinion that the necessity for hospitals and the work and expenditure thereon will be in no way diminished by the Act. At an interview with hospital authorities the Chancellor of the Exchequer has said that the hospitals of the country were essentially a part of the machinery of civilisation, and he could not imagine any country allowing any single hospital to be closed because it was short of cash. This would seem to imply that if the hospitals are not supported voluntarily they will be supported by taxation, which will probably lead to their ultimately becoming State hospitals. After the removal of the infirmary to its present site the board pointed out that £12,000 in new annual subscriptions would be required to enable the institution to pay its way. The response had been only £3220, while during 1911 there had been a further decrease of £563. The in-patients in 1911 numbered 8631 as compared with 5169 in 1908, while the out-patients reached 63,949, as compared with 46,856 in 1908. The number in all departments of the hospital who received the benefits of the charity during the past year totalled 74,540. There has been a remarkable increase in the number of minor casualties, perhaps due to the operation of the Workmen's Compensation Act. They reached 22,654, as compared with 18,381 in 1910. Legacies to the amount of £10,607 have been received during the past year. A medical expert has been appointed to devote his whole time to research in cancer.

Manchester Royal Eye Hospital: Annual Meeting.

The annual meeting of the trustees of this hospital was held recently. Again a large increase in the activity of the hospital has to be recorded. The out-patients admitted were 25,222 at Oxford-road, an increase of 3155, and 14,037 at St. John-street, an increase of 1262. The number of in-patients at Oxford-road was 2008, and the average duration of their stay was 20·5 days. The number of accident cases treated at the two hospitals was 9350, giving an average of nearly 30 a day. This increase of patients, in and out, necessitates a corresponding increase in expenditure. The ordinary annual expenditure now exceeds the ordinary income by £544. Arrangements have been made with the University of Manchester for the appointment of a laboratory steward to the hospital, who will work under the supervision of the professor of pathology of the University. This arrangement is intended to facilitate the examination of pathological specimens in connexion with diseases of the eye. It is also hoped that great progress may be made in the preparation of sera and vaccines for use in the treatment of such diseases. The professor of pathology (Dr. J. Lorrain Smith) is appointed honorary pathologist to the hospital, and will become a member of the medical board. Founded in 1815, the hospital at that time had an expenditure of £202 for the year. Now this expenditure is £7000. Last year out-patients increased largely and increased subscriptions are urgently needed. A certain amount of the increased work was due to the education authorities of the city having taken up the question of the eyesight of school children. The result has been that the children attend the hospital earlier in their career when any visual defect is found. The only legacy received during the year was one of £1000 from Mr. Armitage. A conditional legacy of £130 was left by Mrs. Rose Hylam, the condition being that within 12 months' time two lady members should be appointed to the board of management. In view of their system of government by a board of management of business men, by a ladies' committee who attended to the interior work of the hospital, and by a medical board who gave advice as to the medical part of the hospital, the board of management unanimously came to the conclusion to make no alteration, in which conclusion it was supported by the ladies' committee.

Cats as Transmitters of Disease Germs.

It is well known that cats may be the means of carrying

various forms of infection. The most recent case is in connexion with the cats in the workhouse of the Bolton guardians, who decided to destroy the cats in the workhouse, and accordingly this has been done. Mr. L. A. Buck, the medical officer of the union, after fully investigating, by means of the X rays, the many cases of ringworm among the child inmates of the cottage homes, came to the conclusion that many of the cases were of animal origin. Only cats that are usefully engaged in the store-rooms have been retained. It is hoped that this measure will practically stamp out the disease.

Manchester and Salford Hospital for Skin Diseases.

The annual report states that there is a debt of £858 due to the bank, and therefore the committee appeals for new and increased subscriptions. The income for the past four years has been far from equal to the expenditure, so that the board has been forced to utilise legacies and donations which might have been otherwise added to the permanent funds. The net result is that the board is faced with an annual deficiency of between £400 and £500. At the meeting of the British Hospitals Association held in Manchester in September the opinion was expressed that in consequence of recent legislation the hospitals would suffer. The report states that the board has already received intimation from several subscribers that although they have not up to now refused to subscribe, yet the working of the National Insurance Act will be carefully considered before they can renew their subscriptions. In 1884, when the hospital first opened its doors, there were 632 patients; last year the number reached 9688. The highest number treated in one day during the past 12 months was 262, and the maximum number of attendances in one week was 1212.

Cruel Sports.

Dean Weldon, preaching at the Manchester Cathedral on Jan. 31st, dealt with the relation of man to the lower animals. Man, he said, possessed the express right of taking the lives of animals for his own support and even for his own pleasure. There was no doubt, too, that if it lay within man's prerogative to take the lives of animals, he could not do it without inflicting a certain amount of pain. It was, however, an absolute duty to reduce that pain to a minimum. Man was bound to see that in slaughter-houses the inevitable death of the animal was made as painless as possible. As to sport, a glance over Christian history showed that one cruel sport after another had been condemned at the bar of public opinion. It was at least probable that as civilisation and sympathy advanced, humane, cultured, Christian gentlemen would find their pleasure—their sport, if he might so call it—elsewhere than in the taking of animal life. But he did not wish to condemn sport. With reference to vivisection, the Dean observed that after all every new discovery must be tried on somebody, either man or animal, and if the life of a human being was more precious than the life of an animal it was difficult to sanction sport and condemn vivisection. He held the view strongly that whenever living animals were subjected to experiment in the interests of progressive science it should be done under anæsthesia.

Formal Opening of St. Mary's Hospital for Women and Children.

The new St. Mary's Hospital for Women and Children in Oxford-road was formally opened by the Earl of Derby, the President, on Feb. 9th. The hospital was built and equipped by Mr. E. Reid, acting as the sole surviving trustee of the late Mr. Manassah Gledhill. After completion it remained unused for some months as the necessary money for its upkeep was not available. A year ago the hospital was hopelessly insolvent, but as the result of an urgent appeal to the public to remove this reproach the trustees raised £40,000, and increased their subscription list by £1600 a year. A further £5000 a year, however, is still required to carry on the hospital as it ought to be carried on. The working women of the city have helped by their contributions in pence and halfpence, aggregating a sum of £1000. The hospital contains 111 beds, 86 for women and 25 for children, and already the accommodation is in full use. St. Mary's Hospital has existed for 122 years. During the first year 400 maternity patients were treated, including 72 in-patients. Last year 4500 maternity cases were treated, 800 operations were performed, and 11,300 out-patients received attention. Lord Derby promised to try to obtain Royal recognition for the hospital.

Feb. 13th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Liverpool University: Degree in Hygiene.

THE Council of the University, on the recommendation of the Senate and Medical Faculty, has decided to provide courses of study leading to a new degree, that of Master of Hygiene. The degree will be open only to graduates in medicine, and will be conferred after examination and a course of study extending over a considerable period. It is intended that the degree shall be of a high standard, and it is hoped that graduates desiring the highest qualifications in the branches of their subject affecting public health will avail themselves of the opportunity of working for this degree. The University will still continue to grant the diploma in Public Health.

Annual Dinner of the Medical Students of Liverpool University.

The annual dinner of the medical students of the University of Liverpool was held on Jan. 20th, at the Exchange Station Hotel, under the presidency of Dr. T. R. Bradshaw, the senior physician to the Liverpool Royal Infirmary. Over 100 were present and the speakers included the chairman, Professor A. M. Paterson, Dr. O. T. Williams, and the representatives from the Leeds University. The meeting was a great success.

Chester Infirmary.

The annual meeting of the governors of the Chester Infirmary was held on Jan. 30th, under the chairmanship of the Mayor of Chester. The report of the board of management, the 157th since the establishment of the institution, showed that the number of patients treated during the year 1911 was 9131, as compared with 9655 in 1910. The average cost per occupied bed was £62 6*s.* 1*d.* The total receipts amounted to £6094 10*s.* The total ordinary expenditure amounted to £7097. The board recommended the appointment of an honorary assistant ophthalmic surgeon. Dr. J. R. Thompson, in seconding the adoption of the report, expressed the fear of the managers, in common with that of other hospital managers, as to the effect on the resources of the hospital of the National Insurance Act. It was not for him to criticise the Act. The Act would not come into operation until July, and he was told by those who were capable of expressing an opinion that it was quite possible that, in response to pressure, the time for the Act to come into operation might be postponed, which would give further opportunity to consider matters. There was no doubt, however, that whatever happened the hospitals of the country must be preserved in their absolute entirety. If the Act affected them in the matter of patients it would be out-patients probably, but the beds would be quite as much required in the future as they had been in the past. He understood the Act provided that the Commissioners would be authorised to contribute liberally to hospitals.

The Royal Albert Institution.

Arrangements have been made for the annual election of patients in connexion with the Royal Albert Institution, to be held at Barrow-in-Furness during May next, and the friends of eligible candidates should at once write to the secretary (Mr. S. Keir, the Royal Albert Institution, Lancaster), for forms, as the list of candidates will shortly be closed. Seventy names have already been accepted by the committee, including 29 from Lancashire, 20 from Yorkshire, 5 from Cheshire, 2 from Westmoreland, 3 from Cumberland, 8 from Durham, and 3 from Northumberland. The institution was founded and is supported by voluntary contributions, and for nearly 50 years past has been successfully engaged in caring for and training the improvable feeble-minded of the seven northern counties of England, 84 per cent. of the inmates having been materially improved, in many cases to such an extent as to be rendered capable of earning their own livelihood. The committee are proceeding with a farm colony for 40 additional inmates, towards the cost of which donations amounting to over £1600 have been received, and others colonies of a similar kind will be formed if there be a sufficiently generous response to the committee's appeal for £12,000.

Feb. 12th.

BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

University of Bristol: Markham Skerritt Memorial.

THE late Dr. E. Markham Skerritt did much for the Bristol Medical School. He was professor of medicine, and for many years was dean of the Faculty of Medicine. Accordingly it was thought proper to commemorate his services to the cause of medical education by some definite University memorial. At first it seemed possible to establish a chair of anatomy in his name, but owing to a series of unfortunate mischances the project had to be abandoned; and the committee appointed to undertake the collection of subscriptions has just handed to the University a sum of £337 for the purpose of establishing a biennial prize for original work in medical science. This is an altogether admirable way of perpetuating Dr. Markham Skerritt's memory, as the promotion of original research in medicine was a matter in which he took much interest. Moreover, it is sadly in need of encouragement in Bristol, even more perhaps than in most British centres of medical education.

Bristol Dispensary for the Prevention of Consumption.

A letter has been sent to medical men and others by the committee of this institution, stating that it will be open for patients on Feb. 19th at 2 P.M. Female patients and children will be seen on Mondays and Thursdays from 2 to 5, and men on Fridays from 2 to 5, and also by arrangement on Tuesdays from 7 to 9. No patient will be seen by the medical officer, Mr. O. J. Campbell Faill, without a card or letter of recommendation from his or her medical man or from the medical officer of health. Medical men may, if they wish, enlist the help of the dispensary by writing "dispensary" on the form of notification of tuberculosis under the Infectious Diseases Acts. Patients so recommended will be examined and treated if suffering from tuberculosis, and their homes will be visited and "contacts" examined. Visitors will be received on Wednesdays at 3.30, when the medical officer will explain the working of the institution, which is supported by voluntary contributions. In a footnote to this letter, Dr. G. Parker, who is a member of the committee and also chairman of the Bristol Division of the British Medical Association, says that after the resolution passed by the Bristol Division the institution feels that it can rely on the active support and hearty coöperation of the medical men of the city. Mr. Faill, the newly appointed medical officer, has worked under Dr. R. W. Philip in Edinburgh, and also at the Paddington Dispensary.

Association of Alumni of Bristol University.

This association held a most interesting meeting at the University recently, an exhibition of memorials of eminent Bristolians lent by various collectors being the principal feature. Among these were various manuscripts and autographs of Southey, Coleridge, Longfellow, Richard Hakluyt, Sydney Smith, Hannah More, and others. The object of the association—to bring together past graduates, and thus to maintain their connexion with the University—was fully achieved by this meeting, as it attracted a large company of members.

The Bristol Royal Infirmary.

The annual meeting of the subscribers to the Bristol Royal Infirmary was held on Feb. 12th under the presidency of Sir George White. The medical report stated that during 1911 the out-patients numbered 56,440, and 4712 in-patients were admitted. The financial statement showed the receipts amounted to £17,182, and the expenditure was £18,586. The total deficit against the institution is now £5391. The chairman stated that the Bristol Royal Infirmary King Edward VII. Memorial will be ready in a few months for the reception of 180 additional patients.

The Royal United Hospital, Bath.

The annual meeting of the subscribers of the Royal United Hospital, Bath, was held on Jan. 31st, under the presidency of the mayor. The medical report stated that during 1911 the in-patients were 1590 and the out-patients 15,943, both figures being in excess of the previous year. In addition, 229 patients were treated at their own homes. The financial statement showed that the expenditure was £7120, and a favourable balance of £4 remained at the close of the year. This was due to the fact that legacies, unless especially bequeathed, were treated as income; if this had not been done there would have been an unfavourable balance of £750. The chairman, Mr. Stanley Wills, made a strong appeal for more financial help. He referred to the inadequate support given to the charity, and added that the institution was being worked as economically as was consistent with efficiency.

Bristol Medical Dramatic Club.

The members of the Bristol Medical Dramatic Club are giving performances of the comedy, *Dr. Wake's Patient*, by W. Gayer MacKay and Robert Ord, at All Saints' Hall, Clifton, from Feb. 13th to 17th inclusive. This is the thirty-fourth annual performance of the club, and the profits will be given to the Bristol Orthopædic Hospital.

The Clifton Dispensary.

The annual meeting of the subscribers of the Clifton Dispensary was held on Feb. 6th. The ninety-ninth annual report stated that the financial position was satisfactory, and a favourable balance of £72 remained at the close of the year. The medical report showed that 2617 medical, 313 surgical, and 71 midwifery cases had been treated during 1911. The committee, in appealing for increased support, refer to the fact that the dispensary has now entered upon the hundredth year of its work.

The Somerset Education Committee and Children's Teeth.

At the last meeting of the Somerset Education Committee it was decided, upon the recommendation of the health committee, that the children in the elementary schools should have their teeth examined and treated by a whole-time dental surgeon, at an annual cost of about £400 per annum, on condition that half the cost be defrayed by the parents and private subscriptions, the other half to come from the public funds.

Death of Mr. J. Frederick Parsons, M.R.C.S. Eng., L.S.A.

Mr. J. Frederick Parsons, honorary surgeon to the Frome (Somerset) Cottage Hospital, died at his residence, "Garston," Frome, Somerset, on Feb. 9th. The deceased received his medical education at St. Mary's Hospital, London, and took the M.R.C.S. and L.S.A. qualifications in 1871. After holding the post of resident obstetric officer at St. Mary's Hospital, Mr. Parsons went into partnership with his father, the late Mr. Joshua Parsons, at Frome, and eventually succeeded to his practice. Mr. Parsons was medical officer of health for the Frome urban district and also certifying factory surgeon. He was highly esteemed and respected in Frome and the neighbourhood. His brothers include Mr. Alfred Parsons, the famous painter, and Dr. H. Franklin Parsons, the well-known epidemiologist, formerly assistant medical officer of the Local Government Board.

Feb. 13th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Medical Inspection of School Children in Aberdeen.

Dr. G. Rose, medical officer of the Aberdeen School Board, has issued his annual report, in which he states that the total number of inspections made during the year was 18,418, in addition to the cases sent in by teachers for advice and those examined by the nurses for cleanliness. Altogether a number equalling two-thirds of the school population passed through the hands of the medical staff during the year. Dr. Rose remarks that the routine of school work is undoubtedly disturbed by the details of medical inspection, but that any inconvenience and additional work is most cheerfully borne and undertaken, most of the teaching staff being strongly in sympathy with school inspection, the good results of which are already showing themselves. The staff consists of two medical officers, three nurses, one typist, and one inspector for dealing with verminous cases; the last-named was added this year. Dr. Rose reports on the cleaning regulations and ventilation (the plenum system in most of the schools) favourably, but suggests that the experiment of shutting off the gymnasia from the general system of ventilation should be made in some schools. Dr. Rose remarks that "Physical exercise can be carried out even in a low temperature. It would be better that the

gymnasium should not be connected with the main school building. A building cheaply got up, well ventilated by cross ventilation, and sufficient to afford shelter from the storm is all that is required, and is infinitely better than one where the ventilation is defective, and which forms an entrance hall to the classrooms." Regarding the heating, Dr. Rose reports that considerable variations were found in the temperatures of the different schools. In a few the temperature was too high. He recommends that the temperature of each classroom should be taken three times during each attendance, and entered on a chart placed beside the thermometer. When the chart showed a temperature above or below a certain standard it could be submitted to the medical officer, who could thus exercise a check on the janitor and teacher. Footwear and clothing showed a marked improvement over last year. The heights and weights of children between 5–6 and 13–14, who were all weighed and measured, were of the average for Aberdeen, though differing slightly from the standard laid down by the Anthropometric Society. In conclusion, Dr. Rose remarks that "while some medical men desire as complete an examination of each child as in life insurance, this is an impossibility without trebling the staff, and were it done it would be of doubtful utility. There are so many known and easily recognisable defects to remedy that there is no need to dream of detecting every incipient case of disease and trying to prevent its development. Such dreaming will remain a dream. That already two out of every three children who were examined have had their defects remedied or seen to leads to the belief that in the early future only a small percentage of those suffering will remain uncared for."

Notification of Measles in Aberdeen.

The town council of Aberdeen is to have under consideration the desirability of including measles among the notifiable infectious diseases. The Medico-Chirurgical Society has communicated with the town council regarding the matter, the society having at a recent meeting discussed the very large death-rate among the children of the city during the recent measles epidemic and passed a resolution to the effect that, in the society's opinion, and especially in view of the circular recently issued by the medical officer of health, all cases of measles in children under three years of age should be notified, and that the usual fee should be paid for such notification.

Feb. 13th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Dinner of the Royal College of Surgeons in Ireland.

THE annual Charter Day dinner of the Royal College of Surgeons was held on Feb. 10th in the Hall of the College, the President, Mr. Robert H. Woods, being in the chair. His Excellency the Lord Lieutenant was present. The President spoke of the lack of response on behalf of the Treasury when asked for help for the school of the College. In spite, however, of all lack of public help the school never had more pupils than at present. Mr. O'Connor, Solicitor-General, spoke of the place occupied by the College in the public life of the country; and Dr. D. J. Coffey, President of University College, made a graceful speech, referring to the relations between the College and the medical profession. In the course of the evening a handsome presentation was made to the President and Mrs. Woods in recognition of their services to the College. At the request of Sir Charles Cameron the Lord Lieutenant handed to the President a massive silver cup and to Mrs. Woods a necklet and pendant.

"Phantasms of Life."

Under the above title Dr. Walter J. Smith gave an interesting lecture last week before the Royal Dublin Society dealing with those curious crystalline forms which simulate living beings. While holding strongly to the view that physico-chemical processes did not explain the phenomena of life, Dr. Smith pointed out that there was no known definition of life which excludes certain crystalline formations. The most distinctive functions of life were nutrition, organisation, and growth, and all of these could be exhibited under certain circumstances by crystals. Similarly, they exhibited reactions to stimuli of intrinsic and extrinsic origin. Some of the phenomena exhibited by "flowing crystals" closely mimicked the forms and movements of living creatures, such as bacteria.

Tyrone and Fermanagh Asylum.

It was reported on Feb. 8th that since the last meeting one female patient had died of enteric fever, and that all the other typhoid patients were now convalescent. The resident medical officer reported that while the sewerage system was condemned he could not regard the asylum as being in a satisfactory state. He asked that the permanent staff should be increased, and the committee granted temporarily two nurses and two attendants.

Monaghan and Cavan Asylum.

At a meeting of the committee of management of this asylum, held on Feb. 8th, a resolution was passed protesting against the adjournment of the inquiry into the auxiliary asylum question, which had arisen through the application of the Cavan county council, and by which the accommodation question had been delayed.

High Death-rate in Belfast.

The death-rate for the week ending Feb. 3rd was from all causes 31·1, and from the principal zymotic diseases 2·5. A great deal of bronchitis, pneumonia, and influenza prevails in Belfast at present.

The National Insurance Act.

The National Insurance Act is becoming more unpopular in Ireland, and especially among that moderate sensible class who belong to none of the political parties, and who are dissatisfied with what they remain convinced, all denial notwithstanding, is the political character of the appointments already made under the Act. They fear that the same principle will continue to prevail, as there is such a rush of candidates for further posts, who are basing their claims solely on political services, without any examination check, as in the Civil Service. Further, it is becoming more and more evident that the approved societies under the Act will be sectarian. Last week at a meeting of the Ancient Order of Hibernians (which is entirely political and sectarian, and of which Mr. J. Devlin is the head) it was decided to ask recognition for that society under the Insurance Act; and other religious bodies of various denominations are taking action each to form its own society. The natural result may be that everything will tend to become more and more sectarian, and that Protestant and Catholic will soon cease to work on any common platform in Ireland, while all voluntary philanthropic efforts will cease.

The Irish Milk Commission.

The Irish Milk Commission began its sittings in the City Hall, Belfast, on Tuesday, Feb. 13th. It is to last four days.

The Chancellor's Speech.

The attack made by Mr. Lloyd George on the medical profession in his speech in London on Feb. 12th has had the effect of stiffening the medical profession in Ireland against the Insurance Act.

Feb. 13th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

A Superior Commission on Medical Instruction.

THE President of the Republic, on the report of the Minister of Public Instruction and Fine Arts, has established at the Ministry of Instruction under the presidency of the Minister a Superior Commission on Medical Instruction. The Commission is to report on all the questions submitted to it by the Minister. It will meet twice a year, but can be convened in extraordinary session. All the members have the right to submit to the Minister proposals or representations on any questions within the competence of the Commission, and these are committed to a subcommittee which examines them and, after hearing their authors, should they so desire, advises the Minister, who in turn endorses their report or remits it for the consideration of the Commission as a whole. The 76 members of the Commission were named at the same time by the Minister of Instruction, and include, among others, the vice-rector of the Academy of Medicine,

the Director of Higher Instruction, the representatives of the Faculties of Medicine on the Superior Council of Public Instruction, the doyens of the Faculties of Medicine and of the mixed Faculties of Medicine and Pharmacy, the president and the permanent secretary of the Academy of Medicine, the Director of Assistance and Public Hygiene at the Ministry of the Interior, the Director-General of Public Assistance in Paris, and the Director of the Military Sanitary Service at the Academy of Val-de-Grâce.

Injections of Serum in Meningitis.

At the Academy of Medicine on Jan. 30th M. Netter presented a report on the work of M. Cantas, in which was demonstrated the cause of certain failures in the use of anti-meningococcic serum in the treatment of cerebro-spinal meningitis. In certain cases closures of the spinal canal are found, which prevent the spread of the liquid throughout the whole extent of the cord. In such cases an injection must be made higher up, even if necessary as high as the cervical vertebræ, to obtain the desired success.

Education of the Vital Processes.

The vital functions of nutrition occupied the attention of the Société de Médecine de Paris during the January session. M. Maurice Faure stated that so far back as 1903 he had established the fact that functions such as respiration, micturition, defæcation, and vomiting, were not exempt from the laws of education. These functions were for the most part dependent on the muscles of the thorax, the abdomen, and the perineum, muscles which were perfectly susceptible to education. Even the smooth (*lisses*) muscles of the viscera were not so entirely refractory to education as was commonly supposed, and in the subjects of contractures, ataxy, and atony, useful effects could be attained by appropriate education. M. Laquerrière and M. Nuytten then presented the results obtained by them up to date with the electrical gymnastic method of Professor Bergonié. This method consists in electrically inducing muscular contractions of the whole body, and, it is claimed, has none of the disadvantages of voluntary exercise. It is indicated in various troubles of nutrition, and especially in obesity and in those cases in which voluntary exercise is difficult or impossible. It can be applied also in the case of the asthenic and the vitally depressed. M. Heckel said that he was not absolutely convinced of the efficacy of this treatment; he thought the exercise should be neuro-muscular, and not simply peripheral in the muscular fibre itself. The neuron allowed the functional nervous adaptation so indispensable to the obese and to those of lowered nutrition, who had always more or less nervous insufficiency. Further, it was to be feared that this mode of incomplete exercise would not obviate relapses.

Gift to the French Medical Faculty at Beyrouth.

At the last meeting of the Academy of Sciences Prince Roland Bonaparte informed the President that he had placed at the disposal of the Academy the sum of 35,000 francs for the use of the French Medical Faculty of Beyrouth.

Medical Expert Decisions.

In order to be recognised in a French court as a medical expert, save in exceptional cases, it is requisite to have official recognition by the Courts of Appeal, which every year, assembled in council, inscribe on the lists submitted by the courts of first instance the names of the doctors of medicine on whom they confer office. But it too often happens that justices of the peace, in the case of industrial accidents, select an outsider whom they favour in place of choosing a medical expert from the official list. In such cases the "expert" decision is worthless, and a judgment based on it must be rejected, now that the Fourth Chamber of the Tribunal has declared void the expert decision of an unofficial expert nominated merely by a justice of the peace.

Feb. 12th.

LITERARY INTELLIGENCE. — Messrs. Witherby and Co. are shortly publishing for Mr. P. H. Bahr two important reports, the one on "Filariasis and Elephantiasis in Fiji," and the other on "Dysentery in Fiji." The reports embody the results of a year's study of these subjects in Fiji, and are to be illustrated with plates in colour and monochrone, and charts.

CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

The Turkish Medical Mission to Tripoli.

THE arrest by the Italians of the 29 members of the Ottoman Red Crescent Association on the French liner *Manouba* has raised a most vigorous protest from many quarters. I hear, however, from a reliable source that some of those arrested did not belong to the Association, but were Turkish officers in disguise. The mistake of the Italians was to detain all the 29 members after the identity of over 20 had been fully established. Dr. Kerim Sabati, a member of the Red Crescent Association, now on duty in Tripoli, had telegraphed to Constantinople for reinforcement for the ambulance staff, upon which the above 29 men were despatched. The Turks thought, however, that they could combine what ought to have been purely medical work with political designs. Dr. Kerim now telegraphs that the detention of the medical mission is causing serious prejudice to the efforts of the ambulance corps. The latter conducts its work in the field for the benefit of Turks and Italians alike. Happily, the French-Italian conflict which had arisen over this matter has now been satisfactorily settled. A local newspaper says that the three doctors, who had been submitted to a professional test by French medical authorities, were completely successful. The German Red Cross Mission sent to Tripoli has reached its destination without any hindrance, and is now doing excellent service at the seat of war together with other and various medical agencies.

Cholera Epidemic in Epirus.

Official reports from Epirus speak of a very serious outbreak of the cholera epidemic in various places of that province. Especially distressing is the condition in several garrisons because of the lack of proper treatment and the scarcity of medical men. A veritable panic has taken possession of the inhabitants, many of whom are leaving their homes for Greek territory. Here they are arrested by the authorities and confined in hospitals and lazarets for supervision. The panic created among the soldiers is so great that many of them have deserted and fled in all directions. Last week 17 cases of cholera occurred in the garrison of Yanina, and the Ottoman Government has ordered the establishment of a lazaret near by. The Greek Government is also doing its best to stem the propagation of the epidemic and to reinforce the frontier guards.

The Earthquake on the Ionian Islands.

The details that have reached Constantinople of the last earthquake on the Ionian Islands are very distressing indeed. The catastrophe began at midnight. The shock was of long duration, according to some reports about three minutes. It was followed by several other shocks. The places that suffered most were Zante and Cephalonia, which are supposed to have been the centres of the earthquake. The inhabitants remained in the fields for days. Almost all the public buildings and the majority of private houses have been destroyed at Zante. Human victims were, happily, few in this town. At Cephalonia, however, more than 30 dead bodies were found among the débris of buildings. The shocks extended to the western coast of the Peloponnesus, but without causing much damage. Assistance, medical and otherwise, has been sent to all the places of the visitation. The Greek Government has appointed a Special Commission to collect subscriptions for the sufferers. Private initiative for relief work is very active both at Constantinople and Athens.

Cholera in Aleppo.

News has just arrived of a cholera epidemic at Aleppo. It is rapidly spreading through the whole city. According to official reports about a dozen deaths occur daily, but there, as everywhere in Turkey, the relatives of the patients are attempting to mystify the medical authorities and to hide cholera cases. This is always one of the chief causes of propagation of our epidemics. It is believed that the disease has been brought by pilgrims. The municipal authorities are said to be indifferent, neglecting to take preventive measures. The streets remain dirty, and no disinfection whatever is carried out. There is also a lack of medical men, a usual evil in the provinces of Asia Minor.

Feb. 6th.

JOSEPH, BARON LISTER

Member of the Order of Merit
Fellow and Sometime President of the Royal Society
Knight Grand Cross of the Danish Order of the Danebrog
Knight of the Prussian Order pour la Mérite
Associé Étranger de l'Institut de France
Fellow of the Royal College of Surgeons of England
&c. &c.

Obituary.

LORD LISTER, O.M.,

SERJEANT-SURGEON TO KING EDWARD VII.; LATE REGIUS PROFESSOR OF CLINICAL SURGERY IN THE UNIVERSITY OF EDINBURGH AND OF SURGERY IN THE UNIVERSITY OF GLASGOW; EMERITUS PROFESSOR OF CLINICAL SURGERY, KING'S COLLEGE, LONDON.

LORD LISTER, whose lamented death occurred early on Saturday morning last, Feb. 10th, was one of the most remarkable men who have ever adorned the medical profession. No previous physician or surgeon has ever impressed his day and generation in an equal degree, and he has now gone to his rest full of years and honours, leaving an imperishable name. He will have a permanent place in history as the maker of discoveries which have revolutionised surgery and have thereby conferred inestimable benefits on suffering humanity. In the investigations which led to such fruitful results he had to rely altogether on the promptings of his own genius, unaided by suggestions from any source except a memoir communicated to the French Academy of Sciences on the preservation of watery solutions of decomposable substances. To Louis Pasteur, the author of this memoir, who, however, was not a medical man, Lord Lister at all times most freely acknowledged his indebtedness. Following up the line of thought thus initiated, he showed the conditions which made the difference between success and failure in the majority of surgical operations, and by successive steps he improved the methods of carrying into practical effect the principles then for the first time laid down, until it was everywhere recognised that in the healing art a new era had begun. Lord Lister, who died at Walmer in his 85th year from pneumonia, was ill only four days and the end came without pain.

Lord Lister in Edinburgh days.
(*Reproduced from the frontispiece of the first volume of the Collected Papers.*)

It was a judicious course that on being raised to the peerage Lord Lister did not adopt a territorial title, but retained his family name, which had for many years been so well known to the medical and scientific world. His father's parents were John Lister of Stoke Newington, London, a wine merchant, and his wife Mary Jackson, both of them being members of the religious body known as the Society of Friends. Mr. John Lister died at the unusually advanced age of 98 years. Their son, Joseph Jackson Lister, born in London in 1786, although following his father's business, possessed great scientific aptitude, which enabled him to become a distinguished microscopist and a Fellow of the Royal Society of London. His improvements in the design of achromatic object-glasses for the microscope were communicated to the Royal Society in 1830; they were published in the *Philosophical Transactions*, and have been descibed by most of the authors who deal with the optical theory of the instrument as well as by Lord Lister himself, in the account of his father's life and work which he wrote for the "Dictionary of National Biography"; this memoir will be found in Vol. XXXIII. of that work, published in 1893. In 1818 Mr. Joseph Jackson Lister married Isabella, daughter of Anthony Harris, of Maryport, Cumberland; they had seven children, four sons and three daughters, their son Joseph Lister, for whom so great a future was in store, being born at Upton, in Essex, on April 5th, 1827. Mr. Joseph Jackson Lister lost his wife in 1864 and died at Upton House, Essex, on Oct. 24th, 1869, in the eighty-fourth year of his age.

The district which bears the names of Upton and Upton Park has undergone many changes since that time. Being in the western portion of the county of Essex, between Stratford and Barking, it lies a short way outside the County of London, but is nevertheless included in the Eastern metropolitan postal district. It is now a populous locality partly within the borough of West Ham. Lord Lister's father's house is still in existence; it stands in Upton-lane, Forest Gate, and is now the vicarage of St. Peter's Church, which adjoins it.

Lister's school education was received at Tottenham, after which he spent several years as a student of arts and medicine at University College, London, graduating in the University of London as B.A. in 1847 and M.B. in 1852; in December of the latter year he was also admitted a Fellow of the Royal College of Surgeons of England. During the first 13 or 14 years of his professional career he was busily engaged in histological and physiological work. His first published paper appeared in the *Quarterly Journal of Microscopical Science*, and was entitled "Observations on the Contractile Tissue of the Iris. By Joseph Lister, Esq., B.A." The principal specimen examined was obtained from a patient operated on by Mr. Wharton Jones at University College Hospital, in August, 1852; the volume containing the article was dated 1853, but the paper, which is illustrated with seven camera-lucida drawings, was no doubt written in the previous year, apparently before the author had taken his medical degree. The same volume contains a second paper by him, entitled "Observations on the Muscular Tissue of the Skin. By Joseph Lister, M.B. Lond., F.R.C.S."; it was dated June 1st, 1853, and was written as from University College Hospital, where he held the successive appointments of dresser and house surgeon under Mr. (afterwards Sir) J. E. Erichsen.

His connexion with Edinburgh began immediately afterwards. Mr. James Syme, who had been for nearly 20 years professor of clinical surgery in the University of Edinburgh, had long been recognised as one of the most eminent surgeons in the kingdom; he was, moreover, well known at University College Hospital, where he had held a temporary appointment as surgeon for

a few months in 1848. In order to gain experience under so distinguished an authority Lister proceeded to Edinburgh in 1853, and soon entered on the position of house surgeon to Mr. Syme's wards in the old Royal Infirmary, since replaced by a new building on a different site. Syme was by nature outspoken and tenacious of his opinions—so much so, indeed, that sharp encounters had taken place on various occasions between him and some of his professorial colleagues; Lister, however, held him in high esteem both as an operator and as a clinical teacher, and between them there was a warm friendship only broken by Syme's death in 1870. On April 23rd, 1856, at Mill Bank House, not far from Edinburgh, Lister married Syme's eldest daughter Agnes. The union was a long-continued and most happy one, although not blessed with offspring. Lady Lister (as she afterwards became in consequence of her husband's baronetcy) died from acute pneumonia in April, 1893, while travelling with him in Italy.

Until 1855 he had served in the Edinburgh Royal Infirmary as Syme's house surgeon, but in this year he received the appointment of assistant surgeon, retaining, moreover, his connexion with Syme's wards. He also then began to deliver lectures on surgery in the Edinburgh extra-mural school, a circumstance which led to his name appearing in THE LANCET of Sept. 23rd, 1855, p. 267, as one of the lecturers for the session 1855–56. His home was No. 11, Rutland-street, Edinburgh. Some anecdotes relative to this period of his career, as well as a contemporary portrait of him, will be found in "Looking Back," a profusely illustrated work which appeared in 1907, and consists of a collection of reminiscences connected with the University of Edinburgh. During the seven years of his first stay in Edinburgh he wrote several important articles on histological and physiological subjects. In the *Edinburgh Medical Journal* he published two papers on the Coagulation of the Blood. The *Quarterly Journal of Microscopical Science* for 1858 contained a paper on the Minute Structure of Involuntary Muscular Fibre, read by him before the Royal Society of Edinburgh in December, 1856, and in the same journal there appeared in 1860 a paper on the Structure of Nerve Fibres, written jointly by Lister and his friend Mr. (afterwards Sir) William Turner, who subsequently became President of the General Medical Council. Several other original observations of his were accepted about this time by the Royal Society of London and the British Association for the Advancement of Science; they will be described separately in a later portion of the present notice.

Dr. James Adair Lawrie, professor of surgery in the University of Glasgow, died in the end of 1859, and in February, 1860, Lister was appointed his successor; the post of assistant surgeon to the Edinburgh Royal Infirmary which thereby became vacant was given to Dr. Patrick Heron Watson. Here it may be remarked that during the whole period of Lister's professorship in Glasgow the University occupied the venerable edifice which had stood for centuries on the east side of the High-street; the Royal Infirmary, where clinical instruction was given, was about half a mile away. It was not until 1870, or a little later, that the present University and the Western Infirmary, adjoining one another on Gilmorehill, in the west of the city, were opened, and by that time Lister had become a professor in the University of Edinburgh. While he was in Glasgow the visiting staff of the Royal Infirmary, not including the out-patient department, consisted of four physicians, four surgeons, and two physicians for the infectious wards. The infirmary, which was founded in 1791, has of late years undergone reconstruction without change of site. It was in no way connected with or dependent on the University, except that the professor of practice of medicine (at that time William Gairdner) was *ex officio* one of the physicians. The admission of students for the purpose of clinical instruction was a privilege granted by the directors, the professor of surgery in the university had to depend on their goodwill for election as a surgeon in the institution, and it was only in the second year of Lister's professorship—namely, in 1861—that he was appointed one of the surgeons to the infirmary and given charge of the wards in which a few years later he accomplished work of such tremendous results.

On June 11th, 1863, he delivered before the Royal Society the Croonian lecture on the Coagulation of the Blood. It was published in THE LANCET of August 8th and 15th in the same year. With the exception of articles on Amputation and Anæsthetics in Vol. III. of the first edition of Timothy Holmes's "System of Surgery," Lister's first published memoir on a purely surgical subject consisted of a series of three papers which appeared in our columns in March and April, 1865, describing his method of excision of the wrist-joint for caries. The cases—15 in number—were under his care in the Glasgow Royal Infirmary during 1863 and 1864, and very full details of the method of operating were given. Carbolic acid was used as a caustic in one of these cases, but there is not in the three papers any reference to the great discovery of which he was then laying the foundations, and which was two years later to be given to the world in the columns of THE LANCET. The articles which inaugurated the antiseptic system of surgery were five in number, each of them entitled "On a New Method of Treating Compound Fracture, Abscess, &c."; they appeared in THE LANCET of March 16th, 23rd, and 30th, April 27th, and July 27th, 1867. The first four of them contain the clinical histories of 11 patients suffering from compound fracture; these cases were under his care in the Glasgow Royal Infirmary during the years 1865 and 1866, and were treated by the local application of carbolic acid; the antiseptic was freely applied to the interior of the wounds in order to destroy the air-borne germs which had the property of causing putrefaction; the opening in the integuments was then covered with lint charged with carbolic acid and protected by an external layer of thin sheet metal. In the fifth of these articles the recommendations for opening abscesses were to the effect that a piece of rag from 4 to 6 inches square should be dipped into a solution of 1 part of crystallised carbolic acid in 4 parts of boiled linseed oil and then laid upon the skin where the incision was to be made. One edge of this rag being raised, the part was incised with a knife previously dipped in the oil, and the rag was instantly dropped upon the skin as an antiseptic curtain, beneath which the pus flowed out. For the subsequent dressings a kind of putty was made by mixing common whiting with the carbolised oil, and this, spread into a layer about 6 inches square, was laid over the incision. At the meeting of the British Medical Association in Dublin in August, 1867, a paper on the antiseptic principle in the practice of surgery was read by him and was printed in THE LANCET and the *British Medical Journal*. It does not describe any important modifications in the technical details, but draws attention to the marvellous improvement in the healthiness of his wards since the introduction of the new treatment. Hospital gangrene and pyæmia had formerly made a frequent appearance in two of his wards, but during the last nine months not a single case of pyæmia, hospital gangrene, or erysipelas had occurred in them. In these six papers Lister made several references to two of his house surgeons, each of whom was named Cameron. One of them was Dr. A. Cameron, who is believed to have died some years ago, while the other was Dr. (now Sir) Hector Clare Cameron, who was for many years professor of clinical surgery in the University of Glasgow, a position which he now holds in an emeritus capacity.

On Nov. 30th, 1867, Lister again wrote in THE LANCET, giving illustrations of the antiseptic treatment and explaining the principles on which it was based, while the two first communications to our columns manifesting the satisfaction of other surgeons with the new treatment appeared on Nov. 9th and Dec. 21st, 1867—the authors being respectively Mr. William Pirrie, professor of surgery in the University of Aberdeen, and Dr. John Maclatchy, of Kilmarnock, in Ayrshire. In the course of the next 12 or 14 months the dressings were rendered much more convenient than formerly by the substitution of carbolised shellac for the carbolised putty already described. The putty, although very serviceable, was awkward to handle when spread thinly and could not always be made to retain its position with certainty, whereas the carbolised shellac plaster spread on thin cloth was at once light, flexible, and strong. During the same period a great extension of antiseptic surgery was rendered possible by the introduction of ligatures of silk or catgut, which were absorbed or remained permanently buried in the living tissues. Owing to the great importance of the catgut ligature and the fact that it did not assume its final form until 1881, it will be convenient to summarise in one paragraph the leading points of its development during all these years and afterwards to return to the events of 1869.

Lister's original paper on this subject appeared in THE LANCET of April 3rd, 1869, with the heading "Observations on Ligature of Arteries on the Antiseptic System." In it he described the case of a woman, 51 years of age, whose left external iliac artery he tied on Jan. 20th, 1868, on account of a femoral aneurysm as big as a large orange and reaching somewhat above Poupart's ligament. Silk thread steeped in carbolic acid was used, the ends were cut short, and the wound was dressed antiseptically. Six weeks after the operation she walked for some time out of doors without over-fatigue, having also to descend and ascend three flights of stairs leading to her room. At the same time he recorded a very successful experimental ligature of the carotid artery of the calf, using for the purpose twisted threads of peritoneum at one place and fine catgut at another. He also published drawings showing the appearance, both naked-eye and microscopic, of the parts when examined 30 days after the application of the ligatures, and announced that surgeons "may now tie an arterial trunk in its continuity close to a large branch, secure alike against secondary hæmorrhage and deep-seated suppuration." The catgut ligatures used for this purpose were directed to be prepared by permanent immersion in olive oil containing carbolic acid, to which a very little water had been added. London surgeons, however, did not share these opinions as to the value of the catgut ligature, for eight years later—namely, in 1877—at meetings of the Clinical Society on Oct. 12th and Nov. 23rd, Mr. Bryant, Mr. Christopher Heath, Sir Thomas Smith, and Mr. Maunder reported cases under their care in which after the application of carbolised catgut ligatures there was either secondary ulcerative action, or secondary hæmorrhage, or recurrence of pulsation in aneurysms. In 1881 Lister was president of the Clinical Society and selected the catgut ligature as the subject of his inaugural address, delivered on Jan. 28th in that year. In this address, which fills more than ten columns of THE LANCET, he said that the favourable results which he had obtained with the catgut ligature were probably due to the simultaneous antiseptic treatment of the wounds continued till healing was perfect; this proviso was essential, for under ordinary treatment (i.e., without antiseptics), if there was a sinus leading to the ligature, septic processes would spread along it, and by inducing unhealthy suppuration and ulceration might give rise at last to disaster from hæmorrhage. The catgut ligatures which he had hitherto been using had, however, one disadvantage—namely, that two months at least were required for their preparation, but he had recently obtained an excellent material for ligatures and sutures by merely immersing the catgut for 48 hours in a solution of 1 part of chromic acid and 200 parts of carbolic acid in 4000 parts of water. It was then removed from the solution, dried, and placed in carbolised oil, after which it was ready for use. When catgut treated in this manner was imbedded in the living tissues it began to be superficially eroded by them after the lapse of a fortnight, and there was ultimately a "substitution of new living tissue for the dead old tissue of the catgut."

Lister had been a teacher of surgery for about ten years when he discovered the advantages of antiseptic dressings. In the lecture-room he had a pleasing delivery which was very easily followed by his hearers. His voice, though not loud and not altogether free from hesitation in pronouncing certain consonants, was neither indistinct nor stammering. Never at a loss for a word, he spoke with the calm deliberation which betokens a well-balanced judgment. His features commonly had a placid, contemplative, serious expression which easily relaxed into a smile in the course of conversation. In personal appearance he was of average height and somewhat slender build; he did not use eye-glasses; his hair, which was abundant and dark in colour, was generally worn rather long; except for small whiskers he was clean-shaven. Both in manner and in speech he was uniformly gentle, sympathetic, and totally free from abruptness, affectation, or self-assertion.

In July, 1869, Professor Syme resigned the chair of clinical surgery in the University of Edinburgh and in the following month Lister was appointed his successor. Not long after entering on the duties of his new position he endeavoured to strengthen his antiseptic precautions by means of an apparatus which could deliver a jet of carbolised spray whenever dressings were applied or changed. He also at this time wrote a long paper entitled "On the Effects of the Antiseptic System of Treatment upon the Salubrity of a Surgical Hospital." This paper, published in THE LANCET of Jan. 1st and 8th, 1870, could not but contain some references to the fact that infective surgical diseases had been notoriously prevalent in the Glasgow Royal Infirmary for many years. The directors of that institution, disturbed by the publicity given to these details, thereupon made a luckless attempt to impugn his statements in the form of a letter which appeared in THE LANCET of Jan. 29th. This production, which was signed by Mr. Henry Lamond, the secretary, plainly showed that the directors did not fully comprehend the significance of hospital gangrene appearing in a healthy wound or of pyæmia suddenly attacking surgical patients. They declared that "in their opinion ..... the improved health and satisfactory condition of the hospital, which has been as marked in the medical as in the surgical department, is mainly attributable to the better ventilation, the improved dietary, and the excellent nursing to which the directors have given so much attention of late years." The directors of the Glasgow Royal Infirmary were as enlightened, intelligent, and well-meaning as any similar public body in the kingdom, but they could not be expected to understand that medicine and surgery are progressive sciences; their minds worked in the same way as the minds of the generality of boards, committees, and councils must work when they are betrayed into dogmatising upon insufficient information. Another point which was not at that time raised by Mr. Lamond, but had no doubt received attention from the directors, was the greater expense of antiseptic than of ordinary dressings. We were able to indicate in these columns that in the Glasgow Royal Infirmary the extra outlay in this respect was regarded as of doubtful utility. Lister, of course, adhered to his belief that the use of antiseptics had a powerful effect in preventing the complications known as hospital diseases. Writing in THE LANCET of August 27th, 1870, he stated that having now been in charge of 50 beds in the Edinburgh Royal Infirmary for nine months, he had not as yet had any case of pyæmia or hospital gangrene.

As already mentioned, carbolised shellac had now for some time superseded carbolised putty in the making of antiseptic dressings, and articles on the treatment of compound dislocation of the ankle by means of this lac plaster, combined with oiled-skin protective, were published by Lister in THE LANCET of March 19th and 26th and April 9th, 1870, which afterwards, we believe, appeared in pamphlet form. At the meeting of the British Medical Association held at Plymouth in August, 1871, he delivered the Address in Surgery, giving to his discourse the title of "The Antiseptic System of Surgical Treatment"; lac plaster and other antiseptic dressings as well as the spray apparatus were shown at the meeting. The address was published in the *British Medical Journal*. After doing good service for about six years the lac plaster was in its turn superseded by gauze charged with carbolised resin, and very full directions for the preparation of this new dressing were given in THE LANCET of March 13th, 1875. This memoir was the first of a series of seven articles, occupying altogether 27 columns, which Lister contributed to this journal in that year. They were all headed "On Recent Improvements in the Details of Antiseptic Surgery." The second and third dealt mainly with various methods of employing carbolised oil and drainage-tubes. The fourth discussed the opening of certain abscesses, the sterilisation and use of sponges, and Lister's experimental proof that the septic ferments were solid particles and not some kind of material in solution; this latter subject had, however, been already set forth by him very fully in a paper published in the *Quarterly Journal of Microscopical Science* for October, 1873, with the heading "A Further Contribution to the Natural History of Bacteria and the Germ Theory of Fermentative Changes." The fifth, sixth, and seventh articles of the series were devoted to the use of boric acid as an antiseptic. In 1875 he made a visit to several university towns in Germany, and the close hold that his doctrines had now obtained upon the intelligence of all enlightened men of science was shown by the enthusiastic welcome that he received from various professors.

In this year the meeting of the British Medical Association was held at Edinburgh, the Address in Surgery being delivered by Professor James Spence. Lister was President of the Section of Surgery, and in this capacity delivered an

address dealing with the great improvement in the healthiness of hospitals in which the antiseptic treatment had been introduced. This address was published in the *British Medical Journal*. From this time forward scientific medical opinion was definitely ranged on the side of Lister's theories. His results were beyond controversy, and dissentient voices were disregarded or classed as evidence of a comic, if respectable, conservatism.

In 1876 Lister was nominated by the Crown to a seat on the General Medical Council as representative of Scotland in succession to Dr. James Warburton Begbie of Edinburgh, who died on Feb. 25th in the same year. The nomination took effect as from March 24th, and in the ordinary course would have held good for five years, but in the middle of 1877 he accepted an invitation to come to London; he accordingly resigned his seat as from August 3rd, 1877, and was succeeded on the Council by Dr. Andrew Fergus of Glasgow. During this his second stay in Edinburgh he resided in the first instance for a short time at 17, Abercromby-place, and afterwards at 9, Charlotte-square.

Sir William Fergusson, professor of clinical surgery in King's College, London, and senior surgeon to King's College Hospital, died on Feb. 10th, 1877. He had held two successive professorships in King's College—namely, that of surgery from 1840 to 1870, and that of clinical surgery since 1870; he had also gained all the distinctions which were open to a member of the medical profession. Mr. John Wood at this time filled the chair of systematic surgery in King's College, but on Sir William Fergusson's death two professorships of clinical surgery were created, one of them being given to Mr. Wood and the other to Mr. Lister; the vacant chair of systematic surgery was filled by Mr. Henry Smith. Lister in accepting this appointment stipulated for and obtained separate wards, house surgeon, dressers, and nurses. His first house surgeon at King's College Hospital was Sir W. Watson Cheyne, who came with him from Edinburgh, and in 1882, in his "Antiseptic Surgery," presented an exhaustive view of the subject in its then stage of development.

Lister delivered the introductory address at King's College at the opening of the session 1877–78, his subject being the phenomena known as fermentation, with special reference to the putrefaction of blood and the souring of milk. The causes and nature of lactic fermentation were also very fully discussed by him on Dec. 18th at a meeting of the Pathological Society, and a number of original experiments were shown and explained. A lengthy report of this address will be found in our columns and in the Transactions of the Pathological Society of London. But versed as he was in all pathological problems, it was in clinical surgery that his deepest interest lay. During the two following years two clinical lectures embodying the results of recent experience were published by him in THE LANCET. The first was on a case of excision of the knee-joint and on the use of horse-hair as a drain for wounds; it appeared on Jan. 5th, 1878. In the second, which appeared on Dec. 20th, 1879, he gave details of the progress of two cases—one in which a little boy had been operated on for empyema and one in which a tumour had been removed from a woman's back, leaving a very large open wound. Both of these cases were dressed with carbolised gauze prepared with a mixture of 1 part of carbolic acid, 4 parts of resin, and 4 parts of paraffin, the spray apparatus being brought into action at the renewal of the dressings. In this lecture he also discussed at some length the function of that part of an antiseptic dressing which he called the protective. This was a layer of material employed to protect the healing surface from irritation by the carbolic acid contained in the outer portion of the dressings. It has been said that Lister was already using the protective in 1870; the improved form which he now recommended was made of oiled silk coated on both sides with specially thick copal varnish and afterwards covered with a layer of dextrine so as to ensure its being wetted when dipped into a watery solution of carbolic acid. The test of a properly made protective was that a solution of carbolic acid might be kept in contact with one side of it for three or four hours without carbolic acid being perceptible to the tongue on the other side. In this clinical lecture and also in the course of some remarks made by him on May 13th, 1881, at a meeting of the Clinical Society of London, of which he was then President, Lister alluded to the toxic effects sometimes produced by carbolised dressings. He said that such cases were infrequent in his practice, probably because he did not repeat the direct application of carbolic acid to a wound oftener than was absolutely necessary. At the outset he destroyed the germs which might have gained access to the wound; and the excess of carbolic acid used for this purpose was soon got rid of by evaporation or absorption; this having been accomplished, the wound remained aseptic and free from carbolic acid, being covered by the protective which was impervious to the carbolic acid existing in the external dressings. Some patients, however, were intolerant of even minute quantities of this antiseptic, and owing to this idiosyncrasy a few instances of toxic absorption had come under his notice. For such cases two other very good antiseptics were available—namely, either salicylic acid in the form of salicylic jute, or a gauze charged with a mixture of 1 part of oil of eucalyptus globulus and 3 parts each of gum dammar and paraffin.

On July 1st, 1880, he was elected a member of the Council of the Royal College of Surgeons of England simultaneously with Mr. William Cadge, Mr. Thomas Bryant, and Mr. Thomas Smith; on expiry of his term of office he decided that he would not seek re-election. At the meeting of the British Medical Association held at Cambridge in August, 1880, he took part in two of the discussions and received the honorary degree of LL.D. from the University.

An interesting subject, which has already been touched upon, is the reception given to the new treatment by various leading members of the medical profession. The history of medicine abounds with instances of vigorous opposition to important advances and improvements, and Lister had for several years to encounter much hostile criticism. Within eight months of the publication of his first paper on compound fracture Sir James Simpson, professor of midwifery in the University of Edinburgh, wrote in THE LANCET of Nov. 2nd, 1867, an article five columns in length elaborately proving what was already well known and generally admitted—namely, that Lister was not the first surgeon to use carbolic acid. He, moreover, assured his readers that Lister's methods of preparing and applying antiseptic dressings were not original, but had already been in use for some years by three surgeons in Paris (Dr. Lemaire, Dr. Déclat, and M. Maisonneuve), by Dr. Küchenmeister in Dresden, and by some others. Sir James Simpson's arguments, however, did not make many converts, and his attack on Lister came to nothing. During the next 12 or 13 years many of Lister's pupils trained in Glasgow and Edinburgh practised the antiseptic treatment and spread a knowledge of its essential details, but notwithstanding all the demonstrations of its utility that had been given in the hospitals, in the lecture room, and in the medical press, not a few eminent English surgeons were as incredulous in 1880 as the directors of the Glasgow Royal Infirmary had been in 1870. As illustrations of this it may be sufficient to specify two men of great reputation, one in London and one in Birmingham, each of them proficient in the arts of controversy and exercising much influence on professional opinion. At the meeting of the British Medical Association held at Cork in August, 1879, the address in surgery was delivered by Sir William S. Savory, who spoke with his wonted fluency and eloquence in attack or ridicule of the system of antiseptic surgery. Sir William Savory enjoyed the then unprecedented distinction of being elected President of the Royal College of Surgeons of England for five years in succession, was full surgeon at St. Bartholomew's Hospital from April, 1867, to November, 1891, and afterwards consulting surgeon until his death in 1895, so that his opposition was a serious matter. Mr. Lawson Tait, of Birmingham, though not so officially important a man, was a great surgeon, and his antipathy to the Listerian doctrines was far more unrestrained. Tait was the first professor of gynæcology at Mason University College, and delivered the address in surgery at the meeting of the British Medical Association held there in 1890. A very skilful surgeon and gynæcologist, he proposed several new and valuable methods of treatment and had a remarkable success in abdominal operations, but his attitude towards the antiseptic doctrines betrayed his unlucky limitations. His opinion of Lister's antiseptic method may be inferred from the following extracts taken from two letters. In the first he wrote: "In my experience it was an almost uniform result that wounds dressed after Lister's plan suppurated, and in many cases they sloughed, and though none of the patients died many of the recoveries were anxious and protracted. ..... It is therefore to me conclusively proved that our

improved results in abdominal surgery do not depend on Mr. Lister's principles at any rate." In the second he wrote: "Lister's antiseptic doctrines and practice were based upon a conception altogether false from my point of view. ..... The Listerism of 20 and 15 and 12 and 10 years ago is dead. ..... The doctrines and practices of Lister have been the basis of the strangest surgical craze of the nineteenth century." Savory made no converts, Tait had no following, and gradually the surgeon who ridiculed Lister was seen himself to be ridiculous.

At the International Medical Congress which met in London in the beginning of August, 1881, Lister delivered two addresses—one on August 5th before the Pathological Section on the Relation of Micro-organisms to Inflammation, and one on August 8th before the Surgical Section on the Treatment of Wounds. These two addresses contain what seems to be his first published reference to pathogenic bacteria as a distinct class of micro-organisms (see THE LANCET of Oct. 22nd, 1881, p. 698, column 1; and Nov. 26th, 1881. p. 902, column 1 and footnote). At the end of the first of these addresses he explained his views on the treatment of strumous disease of joints, while the leading feature of the second one was a discussion of the success which in the practice of several surgeons had followed ovariotomy performed without antiseptic precautions. On Oct. 29th, 1883, he delivered before the Medical Society of London an address on the Treatment of Fracture of the Patella. The patients were seven in number, five suffering from recent fracture and two from ununited fracture of several weeks' standing; the fragments were wired, the wire being sometimes removed subsequently and sometimes left permanently *in situ*. The address was published in the *British Medical Journal*, and formed a very practical demonstration of what antiseptics could do; for with the Listerian methods an injury, too often under the older treatment leading to recurrent and permanent lameness, could be absolutely and safely cured.

In December, 1883, he received the honour of a baronetcy.

On Oct. 20th, 1884, he delivered before the Medical Society of London an address on Corrosive Sublimate as a Surgical Dressing. He had already, in the course of a discussion at the Woolwich Military Medical Society on Feb. 15th in the same year, drawn attention to the antiseptic properties of this substance. In this address, which will be found in our columns, he described a great many original experiments devised for the purpose both of testing the efficacy of various antiseptics and also of ascertaining the best means of applying corrosive sublimate. He found that a solution of this substance in the serum of horse's blood, although much less irritating to the skin than a solution of equal strength made with water, was nevertheless powerfully antiseptic. As the result of various experiments with serum solutions he gave the preference to a combination of 1 part of corrosive sublimate with 100 parts of serum. Gauze charged with this in the proportion of 2½ parts of the liquid to 1 part of gauze would, when dried and ready for use, contain from 2 to 3 per cent. of its weight of the mercurial salt. Although very satisfactory as an antiseptic application to wounds, this gauze was somewhat harsh mechanically and was not very absorbent; the manufacture of it was also attended with the difficulty that the necessary serum of horse's blood was not always easily obtainable.

Lister had already publicly stated that his actual practical work in surgery was drawing to a close, when in November, 1889, he delivered two discourses on a new antiseptic dressing—one of them before the Medical Society of London on Nov. 4th and the other before the Hunterian Society on Nov. 27th. Including an account of his method of treating old dislocations of the shoulder-joint, the two articles together occupy nearly 16 columns of THE LANCET. He commenced with a short reference to the serum and corrosive sublimate described, as already mentioned, some five years back, and said that a few weeks after that date he began to experiment with the double salt of bichloride of mercury and chloride of ammonium, familiarly known by its mediæval name of sal alembroth. As compared with bichloride of mercury it was more efficacious antiseptically and much less irritating, but its free solubility rendered it liable to be washed out of the dressings by the discharge from the wound. Lister therefore regarded it as untrustworthy, and concluded his account of it with the following remark: "I may say that I myself have never published anything in favour of sal alembroth dressings; I have never been satisfied with them. It has leaked out that I have used them and they have come into extensive employment, but never with my published sanction." Biniodide of mercury, prepared by precipitating a solution of bichloride of mercury with iodide of potassium dissolved in a weak solution of starch, was a useful antiseptic for applying to gauze, as the starch caused the feebly soluble precipitate to adhere firmly to the fibres; the biniodide was, however, sufficiently soluble in blood serum to become irritating. Lister therefore resumed some experiments which he had already been making with the precipitate obtained by mixing solutions of cyanide of mercury, cyanide of potassium, and sulphate of zinc. This precipitate was an amorphous powder, insoluble in water, but soluble in 130 parts of glycerine, or 3000 parts of blood serum. Its mercury component was soon found to be unexpectedly small; subsequent investigation showed that it was a true double cyanide of mercury and zinc but of an unusual type; an account of its chemical peculiarities will be found in a long paper by Professor Wyndham R. Dunstan, published in the *Journal of the Chemical Society* for 1892. This double cyanide had a remarkable power of inhibiting bacterial growth. Its germicidal efficacy or ability to destroy existing bacteria was inferior to its inhibitory power, but this deficiency was corrected by moistening the dressings with a 5 per cent. solution of carbolic acid; corrosive sublimate must not be employed for this purpose, because it formed with the double cyanide a triple compound which had the defects of being feebly germicidal and highly irritating. Lister found by experiments on his own person that the powder of the double cyanide might be kept applied to the skin for an indefinite time without occasioning any irritation. The powder moistened with a weak solution of corrosive sublimate and rubbed into hairy parts would also render the hairs aseptic. Copious directions for the preparation and use of dressings charged with this precipitate will be found in Lister's own words in THE LANCET of Nov. 9th, 1889, and Jan. 4th, 1890.

At the International Medical Congress held at Berlin in August, 1890, he delivered an address on the Present Position of Antiseptic Surgery. On this occasion he made some observations on the success in abdominal operations achieved by certain surgeons who were well known to be hostile to the use of antiseptics as employed by himself. He also mentioned that carbolic acid had now given place to the less irritating although more efficient solutions of corrosive sublimate, and that the carbolic spray had been abandoned three years previously. He further stated that the antiseptic combination of cyanides of mercury and zinc could now be prepared in a perfectly definite manner; although the new product contained twice as great a percentage of cyanide of mercury as was present in the substance originally used, it nevertheless had no tendency to cause irritation.

At the International Congress of Hygiene and Demography held in London in August, 1891, he was president of the Section of Bacteriology, and delivered the introductory address in that section.

In 1892 the regulation imposing an age-limit made it necessary for him to resign his position as clinical lecturer at King's College Hospital. When making his last appearance in this capacity at the end of July in that year he addressed the students on the Present Aspect of the Essential Parts of the Antiseptic Treatment of Wounds, spoke with some sadness of the termination of his work as a teacher, and reminded them that medical practitioners were under an obligation to labour for the good of their fellow men. In the ensuing session, 1892–93, he received the title of emeritus professor of clinical surgery, being succeeded in the duties of the chair by the late Mr. W. Rose. The authorities of King's College retained his services as surgeon to the hospital for another year, until at a meeting of the council held on July 26th, 1893, he was appointed consulting surgeon.

On Jan. 18th, 1893, he delivered at the hospital in the London post-graduate course an address on the Antiseptic Management of Wounds. As he would in a few months cease to be an active member of the hospital staff, this address, which was printed in THE LANCET of Jan. 28th and Feb. 11th and 18th, 1893, was very important as containing the results of his matured experience of antiseptic surgery. It was not, indeed, his final utterance on the subject, for Sir

Hector Cameron's small book "On the Evolution of Wound Treatment during the last Forty Years," published in Glasgow in 1907, contained an independent section of five pages headed, "Note by Lord Lister." In this "Note" Lister added a little to what he had said in the address with regard to the properties and use of the double cyanide of mercury and zinc, and he made an express reference to this address, without indicating that his views as there set forth had undergone any change. For the absorption of blood or other discharges from an operation wound he preferred sponges to any of the substitutes that had been at various times proposed. For the purification and sterilisation of such sponges, with an especial view to the destruction of both the sporeless micrococci and the spore-bearing tubercle bacillus, he preferred carbolic acid (dissolved in 20 parts of water) to any other germicide. He used a precisely similar solution for purifying the instruments, the hands of the operator, and the skin of the patient, except only in the case of the eyelids, for which carbolic acid was too irritating, and a weak solution of corrosive sublimate was probably the best substitute. In circumstances where it was impossible to exclude septic agencies, such as in operations upon the mouth or the rectum, or in putrid sinuses, or in certain compound fractures, iodoform might be dusted over the cut surfaces of a wound, after mopping with a solution of 40 grains of chloride of zinc in an ounce of water. The usefulness of iodoform was, however, rather limited. The agent which he had found the most satisfactory as the antiseptic ingredient for incorporation with the gauze of the external dressing was the double cyanide of mercury and zinc, this substance being made to adhere to the gauze by mixing it with an aniline dye called rosanilin in the proportion of a quarter of an ounce of the dye to 4 pounds of the double cyanide. Before application to a wound the cyanide gauze must be rendered damp with solution of carbolic acid. The cyanide powder dyed with the rosanilin might also be treated with enough of the 1 in 20 carbolic lotion to make a sort of soft mud or cream which might be applied with a camel's-hair brush to parts where there was very little space between the wound and some source of septic contamination such as the anus. In some circumstances the cyanide powder might possibly be used as a kind of first-aid dressing by dusting it over wounds with a pepper-box. When there was a free discharge from a wound he preferred, as a rule, to remove the first dressing after the lapse of 24 hours, but a longer interval ought to be allowed after certain amputations. Very full directions for carrying out the various procedures were given by Lister both in Sir Hector Cameron's book and also in the numbers of THE LANCET already mentioned.

On April 9th, 1895, at Marlborough House, the Prince of Wales (later King Edward VII.) presented Lister with the Albert Medal of the Royal Society of Arts which had been awarded to him in recognition of his application of antiseptic methods to practical surgery. On July 30th of the same year, in the theatre of King's College Hospital, he was presented with a three-quarter length portrait of himself, painted by Mr. Lorimer, A.R.S.A., and accompanied by an illuminated and illustrated album containing the names of his friends, colleagues, and pupils, who had agreed on this method of showing the affection and esteem which they entertained for him. The presentation was made by Sir John Erichsen, to whom Lister had been house surgeon more than 40 years previously. In the same year he obtained the proudest scientific position open to a man by being elected President of the Royal Society.

When the British Association for the Advancement of Science met at Liverpool in September, 1896, he occupied the presidential chair, and took for the subject of his address the Interdependence of Science and the Healing Art. As the British Association has no medical section communications on strictly medical topics are not received, but biology has for a long time held an important place on the programmes, and he delivered an interesting address dealing mainly with the phenomena of fermentation and bacterial growth, the relation of bacteria to the healing of wounds and to the causation of certain diseases, the results of the application of the germ theory to surgery, the value of vaccination as a preventive of small-pox, and Metchnikoff's observations on phagocytosis. It was not the first time that he had contributed to the proceedings of the Association, for as long ago as 1857, when the Association met at Dublin, physiology being included as a subsection in the Section of Botany and Zoology, Lister read a paper on the Flow of the Lacteal Fluid in the Mesentery of the Mouse; he found that the lacteals, though known to be muscular, did not, in the mesentery at least, promote the flow of the chyle by contraction, rhythmical or otherwise; indigo mixed with the food of the mice passed freely along the intestines, but none of it was ever seen in the chyle.

Lister's elevation to the peerage was the most conspicuous feature of the New Year honours conferred by Queen Victoria in the beginning of 1897, the same year in which she at a later period celebrated the sixtieth anniversary of her accession to the Throne. Nothing was more noticeable than the universal approval which the appointment called forth from all quarters, the press of every party and shade of political feeling being hearty in its praise of the creation of the new peer, whose titular distinctions were manifestly independent of political considerations, because it was under a Liberal administration (Mr. Gladstone's) that he became a baronet and under a Conservative administration (Lord Salisbury's) that he became a peer. He took his seat in the House of Lords on Feb. 23rd, being introduced by Lord Watson and Lord Playfair, and delivered his maiden speech in the middle of May in the course of a debate on venereal disease amongst the troops in India. He did not take any part in political debates, but spoke fully upon the Vaccination Bill in 1898.

On March 29th, 1897, at the Royal College of Surgeons of England, a portrait of him, painted by W. W. Ouless, R.A., was formally presented to the College on behalf of the subscribers. The honorary medal of the College was awarded to him on April 8th, the actual presentation of it being made on June 10th. During the end of August and beginning of September, 1897, the British Association for the Advancement of Science and the British Medical Association held their annual meetings, not in the United Kingdom as usual, but in Canada; Lister was present at both and was in a variety of ways cordially welcomed by the Canadian representatives of medicine and science. On Oct. 8th, 1898, he opened the Thompson-Yates Laboratories of physiology and pathology in Liverpool and received the degree of Doctor of Science from the Victoria University of Manchester. On Feb. 28th, 1899, he was nominated a special foreign member of the Paris Academy of Sciences, and on April 22nd he was again in Liverpool presiding at the inauguration of the School of Tropical Medicine in that city; this school subsequently had at its disposal the Mary Kingsley Memorial Medal, which was founded for the purpose of recognising the work of those who had accomplished much in the cause of tropical medicine, and in February, 1908, the medal was awarded to Lister.

Professor Thomas Henry Huxley, who died on June 29th, 1895, had commenced his professional career as a student in the medical school of Charing Cross Hospital in 1842, and in memory of him a special prize and a scholarship for students in that school were founded; a lectureship was also created, the lecture to be delivered every second year and to deal with recent advances in science and their bearing on medicine and surgery. The first of these Huxley lectures was delivered by Professor Michael Foster, of the University of Cambridge, on Oct. 5th, 1896; the second by Professor Rudolf Virchow, of Berlin, on Oct. 3rd, 1898; and the third by Lord Lister on Oct. 2nd, 1900. Lister's discourse was entitled "Early Researches leading up to the Antiseptic System of Surgery," and narrates the whole story from the chief actor's point of view. The researches in question were pursued during the period of about 12 years between 1852, when he took his degree, and 1864, when he made persistent but unavailing trials of sulphite of potassium as recommended by Dr. Polli of Milan in the treatment of pyæmia. The chief points touched upon in the Huxley lecture were suppuration, inflammation, the coagulation of the blood, and the diversified phenomena presented by the circulation of the blood and the movement of the pigment granules as seen with the microscope in the web of the frog's foot.

At a comparatively early stage in his career Lister's microscopical observations of certain vital phenomena received favourable recognition from the Royal Society of London, and in later years the highest honours at the disposal of that learned body were bestowed on him. As these various events occurred at intervals during a period of more than 40 years it will be convenient to group them

in one or two paragraphs separately from his surgical work. In his student days medical microscopy was very different from what it now is, but he was an adept in the methods of manipulation then practised, and particularly expert in drawing microscopic objects by means of the camera lucida. Some of his papers communicated to the Royal Society have been already mentioned. The first four, written while he was assistant surgeon to the Edinburgh Royal Infirmary, were as follows: (1) An Enquiry Regarding the Parts of the Nervous System which Regulate the Contractions of the Arteries; (2) On the Cutaneous Pigmentary System of the Frog; (3) On the Early Stages of Inflammation; and (4) Preliminary Account of an Enquiry into the Functions of the Visceral Nerves, with special reference to the so-called "Inhibitory System." Nos. 1, 2, and 3 were communicated for him by Dr. William Sharpey, secretary of the society; they were read on June 18th, 1857, and were printed consecutively in Vol. CXLVIII. of the Philosophical Transactions of the Royal Society (the annual volume for 1858), where they fill 96 large pages, and are illustrated by two full-page plates of drawings, both plain and coloured. No. 4 was in the form of a letter to Dr. Sharpey, and was printed in the Proceedings of the Royal Society, Vol. IX. (1857-59), being marked, "Received, August 13th, 1858." On June 7th, 1860, he was elected a Fellow of the Royal Society. On June 11th, 1863, he delivered before the society a Croonian lecture on the Coagulation of the Blood, which, as already mentioned, was soon afterwards published in THE LANCET. In 1880 one of the Society's Royal Medals was conferred on him. In reference to this award Mr. William Spottiswoode, in his presidential address delivered on Nov. 30th in that year, said that "Lister's claims to the honour of a Royal Medal are based upon his numerous and valuable contributions to physiological and biological science during the last 30 years." On Dec. 31st, 1890, Sir William Thomson was elected President of the Royal Society. He was soon afterwards raised to the peerage with the title of Lord Kelvin, and on the completion of the usual period retired on Nov. 30th, 1895. Lister was on that day elected President in succession to Lord Kelvin, and accordingly occupied the chair at the meeting held on Dec. 5th. Although several physicians have been presidents of the Royal Society Sir Benjamin Collins Brodie is the only surgeon upon whom this honour has been conferred except Lister. It is customary for the President of the Royal Society to deliver five official addresses, one at the conclusion of each year of office. In Lister's case the first one was published in the Proceedings of the Society, and the subsequent ones in its Year-book. At the annual meeting of the society in 1902 he received the Copley medal. Replying for the medallists at the dinner usually held on the evening of the meeting, he commented on the unsympathetic attitude of many surgeons towards the antiseptic system in the earlier period of its history, proving that he knew, though his attitude had been throughout so steadily forbearing, that animus had been employed against him. His revenge in this his jubilee year (he was admitted M.B. Lond. and F.R.C.S. Eng. in 1852) was very complete, for most of his opponents' names and all their words had been by this time forgotten. The *British Medical Journal* published on Dec. 13th, 1902, a number especially in celebration of Lister's jubilee of medical work.

Lister's admiration for the researches of Pasteur naturally led him to take a deep interest in the movement for the creation in this country of an establishment specially devoted to the bacteriology of infectious diseases and having objects of a general similarity to those of the Pasteur Institute in Paris and the Imperial Hygienic Institute in Berlin. At a meeting held in London at the Mansion House on Dec. 5th, 1890, an executive committee was formed to take measures for the purpose, and of this committee Lister was appointed chairman. Cambridge was at first considered to be an advantageous centre for carrying on work of this kind, but a site was eventually secured in Chelsea Bridge-road, London, overlooking the River Thames. The new establishment was originally called the British Institute of Preventive Medicine. There was at the outset some difficulty in obtaining a licence from the Board of Trade, but this was satisfactorily arranged, and the articles of association were duly signed at Lister's residence in London on July 21st, 1891, by himself as chairman of the council, Sir Spencer Wells, Sir Henry Roscoe, Sir George Humphry, and others. The work of the institute was begun in temporary premises at 101, Great Russell-street, London, during the erection of the permanent buildings which were not ready for occupation until May, 1898. In connexion with a benefaction bestowed by the Jenner Memorial Committee in 1898, the establishment on Dec. 6th in that year underwent a change of name, being then designated the Jenner Institute of Preventive Medicine. At the annual general meeting of the institute held in June, 1899, it was announced that Lord Lister would be chairman of the governing body. On Sept. 13th in the same year permission was obtained for an alteration of the memorandum of association in consequence of a gift of £250,000 received from Lord Iveagh. After the change of name to Jenner Institute of Preventive Medicine a curious and unexpected difficulty came to light—namely, that a manufacturer of calf lymph carrying on business at no great distance from the institute had already called his premises the "Jenner Institute for Calf Lymph" and was using Jenner's name as a hall-mark for his wares. On account of the similarity of the two names it would have hardly been possible to avoid creating some bewilderment in the minds of the public if the Jenner Institute of Preventive Medicine manufactured calf lymph. The problem was solved at a meeting held at the institute in Chelsea Bridge-road in July, 1903, when a motion to alter its name to "The Lister Institute of Preventive Medicine" was unanimously adopted, and in the course of the next two months the legal formalities necessitated by the change of name were completed.

Lister was on more than one occasion honoured by receiving appointments as surgeon to the reigning sovereign. During his professorship in the University of Edinburgh he became one of Queen Victoria's surgeons in Scotland, but on his removal to London in 1877 he necessarily vacated this position. At this time Sir James Paget was one of the Queen's serjeant-surgeons, and after the death of Sir Prescott Gardener Hewett in 1891 he remained the only one. Sir James Paget having died on Dec. 30th, 1899, it was announced in the *Gazette* of March 20th in the following year that Lister had been appointed to the vacancy; he had already for some time been surgeon extraordinary to Her Majesty. After the death of Queen Victoria, which occurred in January, 1901, Lister was during the first year of the new reign sole serjeant-surgeon to King Edward VII., but he subsequently shared this dignity with a colleague promoted to the same rank.

Lister's eightieth birthday, which fell on Friday, April 5th, 1907, brought to him congratulatory letters and addresses from all parts of the world. At a meeting held at the Royal College of Surgeons of England on the previous day under the chairmanship of Sir Henry Morris, President of the College, it was decided that the anniversary would be suitably commemorated by a republication of Lister's scientific papers which, as he himself said in his Huxley lecture, were "scattered through a variety of media of publication extending over a pretty long period." It was also agreed to preface the volumes with an introduction which, without being in any sense a biography, would enable the various steps in his discoveries to be rightly appreciated. This most valuable contribution to the history of surgical progress was completed in 1909, the collected papers being published in two substantial volumes.

In 1908 he was invited to accept the position of Chancellor of the University of Glasgow, but felt himself compelled to decline the invitation because of the feeble state of his health; in that year, however, he published in THE LANCET and *British Medical Journal* three important original papers which had not previously been in print, although parts of them had been written several years before. The first one appeared on Jan. 18th, and contained a description of the preparation of catgut for surgical purposes; the catgut was directed to be placed in a solution of chromium sulphate prepared by mixing solutions of sulphurous and chromic acids, and after 24 hours' immersion was to be dried on the stretch. The second paper, which appeared on April 11th, was on the treatment of fractures of the patella of long standing; and the third, which appeared on June 27th, consisted of remarks on some points in the history of antiseptic surgery. They were the last on the long list of original articles which he had contributed to THE LANCET during a period of 43 years.

Among the various tokens of general public esteem bestowed on him, mention may be made of the freedoms of some municipalities. On June 15th, 1898, he received

the freedom of the city of Edinburgh, and on June 28th, 1907, the freedom of the city of London. On Jan. 21st, 1908, he was enrolled a freeman of the city of Glasgow, a letter from him being read expressive of his regret that illness prevented him from being present at the ceremony. As mentioned in the early part of the present article, Lister's birthplace is now included within the extra-metropolitan borough of West Ham, which is of comparatively recent creation, and at the annual meeting of the council held at Stratford in Essex on Nov. 9th, 1908, his acceptance of the freedom of the borough was announced by the mayor, who at the same time read a letter from him thanking the council for their courtesy; on account, however, of the weak state of his health it had been found necessary to dispense with the usual ceremonies.

In addition to the qualifications which originally admitted him to the medical profession, Lister held various honorary degrees from the Universities of Edinburgh, Dublin, Glasgow, Oxford, Cambridge, Würzburg, Bologna, Budapest, Geneva, and the Victoria University of Manchester. He was a Fellow of the Royal Societies of London and Edinburgh, of the Royal College of Surgeons of Edinburgh, of the Faculty of Physicians and Surgeons of Glasgow, and of University College, London; a laureate of the French Academy of Sciences; an associate member of the French Institute and of the Paris Academy of Medicine; a corresponding member of the Paris Surgical Society; and an honorary member of the American Academy of Arts and Sciences. A peer and a member of the Privy Council, he also possessed the British Order of Merit, the Grand Cross of the Danish Order of the Danebrog, and the Prussian Ordre Pour le Mérite.

We have purposely confined this obituary notice of the world's greatest surgeon to a list of the actual things that he did with the dates on which he did them. No panegyrics are needed: the greatest modern Englishman is dead.

Messages of sympathy have been received by Lord Lister's family from the King, from Queen Alexandra, and from other members of the Royal Family. The first part of the funeral service will be held to-day (Friday, Feb. 16th), in Westminster Abbey, at 1.30 P.M., and the interment will take place privately at Hampstead Churchyard. The pall-bearers will be: Lord Rayleigh, Lord Rosebery, Lord Iveagh, Sir Archibald Geikie, Sir Hector Cameron, Sir W. Watson Cheyne, Mr. Rickman J. Godlee, and Professor F. M. Caird. The offer of burial in Westminster Abbey was declined by the executors, because of Lord Lister's expressed wish to be buried beside his wife.

The portraits which we publish will be recognised as reproductions of the frontispieces to Lord Lister's Collected Papers. The plate was taken by Messrs. Barrauds, Limited, and the inset illustration by Messrs. Moffatt, of Edinburgh.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Genealogy of the Austro-Hungarian Heir-Apparent.

THE well-known historian Otto Forst has recently published an elaborate monograph on the genealogy of the Archduke Francis Ferdinand, heir-apparent to the throne of Austria-Hungary, and several parts of the work will possess much interest for medical readers. The antecedents of the Habsburg family are very complicated, for numerous families of different nationalities have a place in the history of this famous and ancient house. The genealogical table of the Archduke Francis Ferdinand, who in due time is expected to succeed to the throne of his uncle, the present aged Emperor, contains 1204 ancestors, many of whom belong to more than one of the names mentioned, as the Habsburgs at various times frequently married into families of the same line. There are 112 different families altogether, from whom the archduke can claim descent. Of these, 71, or 63 per cent., were of German nationality, 20 were Polish, 8 were French, 7 were Italian, and 1 each belonged to the Russian, Scotch, Swedish, Roumanian, and Hungarian nations. It may be mentioned that all the ruling families of Germany are represented in the table, the Bavarian family of Wittelsbach predominating with 52 persons, who appear 204 times in the list. This was naturally to be expected, but at the same time the records show that 57 families, or about 50 per cent., had a place among the less important orders of the nobility, whilst some of the ancestors even belonged to the lower ranks of the population. Another interesting feature of the genealogy is the fact that the medical profession is represented, for the archduke is a descendant of the Medici, the famous Italian rulers, who had several pills in their coat of arms in memory of their ancestral occupation as apothecaries and medical men.

Proposed Reform of the Medical Curriculum.

The present system both of teaching and also of conducting examinations in the course of medical education is not very congenial to the majority of the students in this country, and several representations explanatory of their views have been sent to the Ministry of Education within the last few years. The principal changes desired by the students' committee are as follows. The examination on biology, botany, and chemistry should take place at the end of the second or third semester instead of one year later, as hitherto, so as to give one year more to clinical study. The examinations should last longer than the 15 minutes now granted to each candidate, and should be of a more general character than hitherto. Instruction in several branches of medicine, which hitherto has been only optional, should be made compulsory, the systematic teaching of otology, physical therapeutics, and serology being especially wanted, as their importance was growing daily. A final hospital year should be made compulsory before the student could graduate at the University, as is the rule in Germany. The students find much support in their endeavours amongst the professors and the profession generally, and their requests will most likely be complied with before long, as they do not involve any considerable expenditure of public money.

The New Scale of Prices (Arzneitaxe) for Drugs.

On Feb. 1st a new scale of prices for drugs came into force in this country, in spite of the opposition by the Krankencassen, which will find it a heavy burden on their finances. Pharmacy in Austria is controlled by the Government; the drug-stores are not only limited in number, but even the premises which they occupy are restricted as regards local situation, and the prices of the drugs are also fixed by a Government Order. The increase of prices is nearly universal for all drugs and remedies, the advance being from 40 to 100 per cent. above last month's prices. The alkaloids are now twice as dear as formerly owing to the manufacturers having organised a "trust" in this branch. Thus, for instance, a gramme (16 grains) of codeine now costs 1*s.* 8*d.*, whereas formerly it was 10*d.* Extract of opium has become dearer by 50 per cent.; ipecacuanha root is also dear. Phenol costs now a penny per gramme which formerly cost a halfpenny. Morphine has been raised from 7*d.* to 1*s.* 4*d.* per gramme, and bromide of sodium is dearer by 35 per cent. Ether for inhalation as an anæsthetic, menthol, and digitalis are now dearer by 50 per cent., but chloroform has become cheaper. As compensation for the increase of the price of the drugs, the charge for manipulating them (mixing, powdering, and dissolving in liquids) has been lowered, so that the public will not have to bear the full burden of the rise of prices. The pharmaceutical chemists still find that their business is not satisfactory, for the numerous ready-made preparations are so much asked for by the public that the profit made on the prescriptions dispensed in accordance with the old style is insignificant. The apothecaries would therefore like to restrict the sale of the ready-made preparations, as they derive little profit from it. On the other hand, the Krankencassen urge their medical officers to prescribe the necessary remedies in the cheapest possible way, to substitute equivalents for expensive drugs, and to make as little use as possible of alkaloids. The result is that the druggists find themselves in an unpleasant position, and suggestions have already been made to the effect that pharmaceutical businesses should be turned over to the Government and made a monopoly, like the sale of tobacco and salt in this country.

Clinical Material in Vienna.

In the General Hospital of Vienna, and in the other hospitals of this city where medical students receive instruction, over 34,000 in-patients were admitted in the year 1911, and their diseases were explained to, and watched by, the students. The number of new out patients in the same institutions was

a little over 100,000 that year; minor operations on all parts of the body were performed on out-patients and in a good many cases by the students themselves. Some 3000 post-mortem examinations were conducted in these hospitals—with us there is only very little difficulty in obtaining permission for such examinations in the case of a patient dying in a hospital—and the same number of births happened in the two obstetric clinics only. Thus, there was plenty of material for the instruction of the students, as well as for post-graduate classes and special courses. For practising surgical operations on the dead body there is ample opportunity in this city.

Feb. 10th.

THE NATIONAL INSURANCE ACT.

LECTURES ON THE PROVISIONS OF THE ACT.

THE secretary of the Insurance Commissioners has given notice that the National Health Insurance Commission (England) are organising a series of lectures in London with a view to explaining in detail the provisions of the National Insurance Act to officials of organisations likely to become, or assist in the formation of, approved societies. Each course, it is said, will consist of a sufficient number of lectures to cover the whole Act, so far as it relates to health insurance. Afternoon and evening courses have been arranged. Societies which desire that their responsible officials should attend these courses are requested to communicate at once with the secretary to the National Health Insurance Commission (England), Buckingham Gate, London, S.W. Where sufficient demand is shown to exist the Commissioners hope to arrange similar courses of lectures in provincial centres.

The recent declaration made by the Chancellor of the Exchequer as to the position of the medical men under the Act will require a good deal of explanation from the lecturers, if they are to do their duty and make clear those parts of the National Insurance Act which have reference to the medical profession.

"AN APPEAL FOR A STRONG BUT MODERATE POLICY."

Under this title a circular letter has been issued to the medical profession by a number of practitioners "attached to no particular party and committed by no pledges to support or oppose the present Council of the British Medical Association." On the one hand, they declare, is the so-called "No service whatsoever" policy of the *Practitioner* and of certain other bodies outside the British Medical Association. On the other hand is the policy already approved by a considerable number of divisions of the Association, including the general body of Scottish and Welsh Divisions—namely, "No service unless the six points and adequate remuneration are first definitely assured by the Commissioners in their regulations." The signatories believe that the former policy would be fatal to the interests of the profession, while the latter would lead to certain victory. They maintain that it is a delusion to suppose that the profession could by the former policy prevent the Act from coming into operation, or even prevent the medical benefits from being given in one form or another. It is too readily assumed, the circular continues, that if the profession refused to form panels, a whole-time service would be attempted. The Commissioners may also "suspend the benefit," giving the insured the equivalent in cash. In such case the approved societies, strengthened in numbers and in prestige, would undoubtedly undertake the organisation of separate medical services. They would be free from any of the restrictions which the Act places upon the Insurance Committees. They would be free to appoint doctors and dismiss them at their pleasure. They could make individual bargains with doctors, playing one off against another in the way that has produced all the abuses of cheap contract practice in the past. If the profession began by putting their case before the Commissioners and the public in a reasonable way, and their reasonable demands were refused, they would be in a strong position to resist. But if the profession began by refusing to negotiate, public sympathy would undoubtedly be alienated. The circular next asserts that the published opinions of counsel show conclusively that the six points can all be obtained under the Act as it stands. But in existing conditions no person or persons should be endowed with plenipotentiary powers. Whatever negotiations may take place, the complete control must be kept by the rank and file of the profession in their own hands. Any committee appointed to put the case for the profession before the Commissioners should be appointed for that purpose only, and should have no authority to settle terms. The circular was sent out at first with 52 signatures, and further names have since been added.

THE BRITISH MEDICAL ASSOCIATION.

In preparation for the Representative Meeting on Feb. 20th and 21st, at the Guildhall, London, many local divisions have already met, and some have favoured us with the results of their consideration of the Council's report and of the recommendations which we printed in our issue of Feb. 3rd. The information so far made public as to the intentions of the divisions has, however, been so partial that it would be unfair to draw any broad conclusion from it.

The Reform Committee of the British Medical Association have now drafted the Bill "to Amend the National Insurance Act," whose principal headings we published in advance last week. This amending Bill has been prepared by counsel. The Reform Committee recognise that it is outside the range of measures which can be brought forward by private Members, and they issue it as a definite scheme containing the minimum demands of the profession.

THE MEDICAL FEDERATION, LIMITED.

About 250 practitioners assembled at the Royal Hotel, Bristol, on Feb. 13th, to hear of the progress made by the project to which the Bristol Division of the British Medical Association has committed itself. The Federation is a limited company which has been registered under the Companies' Consolidation Act, 1908, with a provisional directorate composed of the executive committee of the Bristol Division of the Association. Its officers also are officers of the Association Division. At this meeting Mr. H. F. Devis, secretary to the Federation, explained its origin and its purposes. He showed that the movement is in no sense opposed to the Association, that on the contrary the two are in close touch with each other, and that success on the part of the Federation will go far to consolidate the Association. In a word, it is designed to collect quickly a large fund out of which medical men suffering financially through obedience to the advice of the Federation may be fully indemnified. It has been so contrived that it can be amalgamated with the British Medical Association or with any other body having as its chief aim the consolidation of the profession for purposes of defence. The promoters of the scheme anticipate that its membership will soon become co-extensive with that of the Association, since it offers an efficient fighting weapon. As soon as the movement attains national proportions the present provisional government will be superseded by a more widely representative one, and at the same time the Federation will be able to undertake a definite line of action in regard to the present crisis. It is announced that the scheme has been pronounced financially sound by experts to whom it has been submitted. After questions had been answered by Dr. T. M. Carter, the chairman, and Mr. G. Scott Williamson, managing director of the Federation, a resolution of confidence in the management was carried unanimously.

MR. LLOYD GEORGE AND THE MEDICAL PROFESSION.

The Chancellor of the Exchequer addressed a meeting of supporters of the Government at the London Opera House on Feb. 12th, and in the course of a speech of an hour and three-quarters' duration made the following reference to the medical provisions of the Insurance Act.

They talked about an amending Act, said Mr. Lloyd George. By all means; nothing was perfect, even in a Liberal House of Commons. But let them get on with the really good things in the Act and all these things would be added unto them. The Tories were doing their best to stir up the doctors to deprive the workmen of the only medical aid which many of them could afford in time to save their lives. A more dastardly enterprise no human being could conceive, and when they stood themselves, as they all had to stand in turn, in need of medical assistance, he was afraid their action now would not do much to relieve their anxieties. He wanted to tell the truth, the whole truth, in this matter, and spare not the false prophets. What about the doctors? He proposed to give them a perfectly frank statement of the Government's position, and he was confident that so long as the doctors did not mix up business and politics it would satisfy them and

every reasonable man among the medical profession. What was the position? A great deal was said about contract practice. What was contract practice? It was an undertaking whereby the doctor engaged to provide medical treatment for a man at a flat rate—it might be 4*s*., 5*s*., or 6*s*., or some other figure per annum. Sometimes it was a flat rate by which the doctor undertook to cure the whole of a man's family. In some districts it was 3*d*. a week, in others 4½*d*. per week. It varied. Contract practice might be good or it might be bad; it had not been created by the Insurance Act. More than half the workmen of the country were cured now by contract—more than half, when they took all the various methods of contract cure into account. Contract practice had its advantages as well as its disadvantages. What were its advantages? It avoided the necessity a doctor was under when he was dealing with a man earning a small weekly wage of sending him in a big bill after a long illness and getting paid in driblets or not getting paid at all, which unfortunately was very often the case. After all, no doctor wanted to be on what he might call "judgment summons terms" with his patients. No professional man he ever met cared to keep account books. They hated it. A doctor did not want to take up his time with the worry of keeping an account, of being paid 5*s*. on account of a bill of £10 and of receiving another 6*s*. in the street perhaps, putting it down, making up the balance, and sending it in at Christmas. He would rather not. So in the working-class districts of this country they had devised this method of contract practice of saying, "Give me 4*s*. or 5*s*. a year and I will cure you of all the ills that flesh is heir to." That was one advantage. There was another advantage for a doctor. It was a kind of retaining fee for the family practice. If the doctor cured the head of the family for 4*s*. he would cure the rest of the family for a good deal more. He could send in bills for the rest of the family. He did not say the doctor would charge more, but even if he did, and he (Mr. Lloyd George) thought possibly he would, there was this advantage in the bargain—that where the head of the family was ill there was no one to earn, whereas if someone else in the family was ill the earner of the family was there to pay the bill. It was a double advantage. It was an advantage to the man himself, and it was an advantage to the doctor who was building up a practice.

What were the disadvantages? It was underpaid. The doctors had themselves to blame for that. He had read a speech by his friend, Mr. Handel Booth, in which he described very vividly the under-cutting, the under-selling, the under-bidding that went on very often between doctors. They would not be surprised to hear that Scotsmen had taken full advantage of it, and that the result was that in Scotland the average rate of pay in every contract district was decidedly lower than in England. He saw a case in an important city like Aberdeen where a doctor undertook contract practice for 2*s*. 6*d*. The average in England was 4*s*. That was thoroughly bad. Underpaid work was shoddy work. It was not to the advantage of the patient or of the doctor. It was far better for the doctor to feel that he was fairly treated and getting a fair wage for the very difficult, delicate, responsible work which he had to accomplish. All this was bad. But he was not responsible for it; the Insurance Act was not responsible for it. The Insurance Act did not perpetuate it, did not extend it, and certainly did not create it. In so far as the Act was concerned, all they had done was to provide substantial funds which would increase by a very large percentage the pay the doctors were now getting for contract practice. He would put the doctors' grievances. The doctors had three great grievances, and he would say at once that he sympathised with them. The doctor's first grievance was that he objected to what he called society control. There were many members of Friendly Societies present, and he was sure they would bear with him while he dealt with this point. The doctors' complaint was that they were under the domination—or, as they put it, under the heel—of the Friendly Society, that it imposed upon them harsh terms. He was not going to express any opinion upon that. If it was true it was a real grievance. He knew that Friendly Society men would instantly protest; it was useful to remind doctors that there were two sides to the question. The second grievance was this: the doctors said, "We don't mind attending men who are earning low wages on contract terms, but we do object to well-to-do people creeping into the Friendly Societies and claiming to be treated on the same terms as the labourer earning 15*s*. a week." He had analysed many of the Friendly Societies of the country and he found they were by no means confined to working-men; there were tradesmen, farmers, publicans, schoolmasters, and professional men among the membership, and the doctors said it was unfair to expect them to treat these men at 4*s*. a head. He would tell the audience why the doctors said that. He was sure the profession would not quarrel with him when he made this statement. The doctor's bill was charged at a scale which had reference to the means of the patient. He did not charge a workman the same fee for a visit as he would charge a well-to-do tradesman or a professional man. The doctor said very truly, "It is because I am able to charge the well-to-do patients more that I am able to treat the workman for less." That was the doctor's case.

What was their third grievance? They said there were districts in England and Scotland and Wales where there was no contract practice at all at the present moment, where the doctors had refused to treat the patients on contract terms, and where the ordinary relations existed between doctor and a patient, where the doctor sent in his bill for time, attendance, medicine, and so on. There were districts in Lancashire—working-class districts—where they had no contract practice at all; there were certainly a very large number of rural districts where there was none, and doctors said, "Why should you force this obnoxious contract practice into districts where it does not exist at present?" He would give his answer to the doctors' grievances.

The first complaint was that they were under Friendly Society control. Under the Act they were no longer under the control of the Friendly Societies. There was an exception under what was known as the Harmsworth amendment, and he commended that amendment to the notice of certain newspapers which had taken full advantage of it to create trouble between the doctors and the Government. He would remind them that most of the trouble had arisen through the Harmsworth amendment, but that exception simply dealt with existing rights, and did not deal with the bulk of the insured persons. It did protect existing institutions, and he stood absolutely by that amendment. Speaking on behalf of the Government, whatever happened they declined to budge from that amendment. Dealing with the new practice that came into existence under the Act, what happened? The Government had set up an independent authority. It was true the insured persons constituted a majority, but that was only the very essence of things. They could not hand over to a committee power to spend money they were not responsible for finding. They must give the majority on a committee to persons who were responsible if any deficit arose. There were on this body representatives of the Government, of the County Council, and of the doctors. The committee could not arrange terms for paying the doctors without consulting the Local Medical Committee, representing the whole of the doctors in that district, and as though that was not enough an appeal had been allowed to the Insurance Commissioners upon the whole of the terms. Was not that an improvement on the present system under which the doctors dealt face to face with the societies without any appeal to anybody?

The doctors' second grievance had reference to the income limit. What had the Government done there? It had empowered the Insurance Committee to fix an income limit in a district, and as the Insurance Commissioners had full powers with regard to approving contracts they would have a word to say as to that. He wanted to give one word of warning—the fixing of a national income limit was impossible. Take the mining districts. Suppose an income limit of £2 was fixed, and they said that no miner earning over that should be treated on contract terms. That was a departure from the existing system and they could not work it. This year a miner might be earning under and next year over £2. On the other hand, they had a district where very few workmen earned anything like £2 a week. What happened if a man was outside the income limit? Was he to be left without any doctoring at all? Special provision was made for him, and that led up to the doctors' third point, that in some districts there was no contract practice—that the doctors vowed they would not submit to it. Under the Act they need have none. What happened? The money which was set aside for doctoring would be paid into a general pool in that area. The doctors would attend to their patients on exactly the same terms as of old, and would send in their bills as against that general pool. If there was a balance the workman would have to pay it. Of course, the local medical men must form some kind of committee to prevent any unfair charge upon the funds by one of their number. No doctor was forced by the Act to take contract practice; no patient was forced to take a doctor on contract unless he wished to. Every doctor who had a contract practice and wished to carry it on would get 50 per cent. more from his patients.

That was the position, and what were the doctors doing? He had no word to say against the British Medical Association, which represented the general practitioners of the country. The Association passed a resolution the other day that it did not see its way to meet the Commissioners until it had first of all had a meeting of the Council. The Association had been criticised a good deal by its own supporters, and it was naturally afraid to commit itself until it had a new meeting of the Council and heard what the doctors of the country wished it to do. Therefore the Association excused itself when an invitation was sent to them by Mr. Masterman. He was not complaining of that; he did not think the action of the Association was unreasonable. But he did not think that quite applied to the Royal Colleges of Surgeons and Physicians, who sent a curt, undignified, discourteous refusal to meet a Government department to discuss matters affecting the profession which they officially represented. These Colleges were formed under a charter, under an Act of Parliament, and when they refused an invitation of a Government department to discuss matters affecting the body they had been called into existence to represent, it was an example of rude ineptitude which was utterly without parallel in the history of the country. There was not a strike committee in the land which would have demeaned itself in that way. The Colleges said the Act was unworkable; the finance was inadequate; it was no use discussing it. That was the very reason why they should discuss it. Why did they not come and point out where the measure was inadequate? Why did they not come there like men and show where the deficiency arose? Why didn't they, if they knew, point out where the Act could be amended? The Commissioners were there to listen to all kinds of suggestions, but to refuse to appear there was behaviour of so extraordinary a character that it showed the societies absolutely unfit for the position which they assumed. For the future negotiations would be conducted with societies that really were prepared to discuss solemn and important matters like business men and were prepared to treat Government departments without regard to their political complexion.

The doctors said, "It is perfectly true you have all these conditions to protect us, all these safeguards; but the finance of the Bill is too limited, it is too insufficient, and there is no scope for negotiations." He had two answers for that. Doctors who were already engaged in contract practice could get 50 per cent. more than they were getting now; doctors who were not engaged in contract practice need not take it for the future. The only thing that would happen to them would be they would charge exactly what they were charging now and would send their bills in as now. The only thing was, there would be a fund to help their patients pay the bills. Surely they did not object to that? He wished there was a body like that to pay lawyers' bills. If all the doctors of the kingdom contemplated dropping their present methods of private practice and entering into contract arrangements with their patients, they might say the finance was inadequate. The question was open to argument, and the Government would listen to the doctors. All they had to do was to demonstrate to the satisfaction of the Commissioners that the finance provided was unsatisfactory. The Commissioners would give every consideration put before them impartial and careful attention, and if the Commissioners were satisfied that the case was made out, on their recommendation it would be the duty of the Government to advise Parliament to find all money necessary to provide a satisfactory medical service for the insured people of the country. But merely to send stiff and discourteous letters declining to discuss with a Government department the best methods of dealing with the question would meet with the reprobation of every business man. The Government was prepared to listen to every fair suggestion—not wild and extravagant demands; one gentleman who represented a certain section sent in a bill for an additional three millions. It was not bringing the demand within proportions that were debatable. Any fair proposal they would consider.

What would happen if the profession followed the advice of its extremists and declined to discuss terms, refused to administer the Act, to recognise committees set up by a statute of the realm, if they defied the law of the land, and said they would have nothing to do with it—

what twould happen? Nothing! Except this—all the safeguards inserted in the Act for the protection of the medical profession would be wiped out at once. It was assumed by those critics of the Act who had been stirring up the doctors to do foolish things that the moment they refused to what they called "work the Act," that it was as dead as Queen Anne The Act would be as alive as ever, but the safeguards for the protection of the profession would be dead. One of the troubles they suffered from was that there were men trying to work various parts of the Act without ever reading it, and those who advised the profession to take that extravagant course could never have read it. Did they really think the Government was so simple that it had not provided for a contingency of that sort? Did they look like it? They had just overlooked one little provision of the Act—that the Government had large "suspensory powers." What did that mean? (A voice: "Hang the doctors!") It might serve, Mr. Lloyd George retorted, to hang those who gave the doctors bad advice. Did the use of the suspensory powers mean that the benefits of the Act would come to an end? The 10*s.* a week, the 5*s.* a week, the consumptive benefit, the maternity and medical benefits would all go on. The insured persons would not be deprived of benefits. What would happen? The money allocated for medical benefit would be handed over to the insured persons through their societies. The doctors who had been compassing sea and land to get away from the Friendly Societies would suddenly find themselves face to face with them once more, and through their own action! There would be no Local Insurance Committee to arrange terms, no committee upon which the doctors were represented, the Societies would not be compelled to consult the Local Medical Committee, there would be no appeal to the Commissioners. All that would be suspended. How would a strike avail under those conditions? Would the local doctors send word to the committee on which their own patients were represented that they declined to meet them, that they would not discuss terms with them? It must be remembered it would not be Friendly Societies merely, but trades unions, industrial insurance companies, which would be dealing with money handed over to them bodily to treat with the doctors. Take the man who had a contract practice—the doctor for the local Oddfellows or Foresters—what would he do? He had worked up a practice laboriously, he had got hold of the heads of the family and had got the rest of the family through them. Was he going to say to the Oddfellows or Foresters, "I am going to throw up my practice"? Was he going to throw up the work of years and allow other doctors to scramble for his practice, and scramble with them under this disadvantage—that he would have quarrelled with his patients? Take the case of a man who was attending a works staff. Was he going to say, "Where do you get your money from? Is it true that there is a subsidy from the Insurance Fund?" The reply would be, "Yes, of course there is." "Well, then," the doctor would reply, "no more works staff for me! I won't touch it if it savours of National Insurance; they can take the unclean thing away." So the doctor would throw up his practice. Could they not see him doing it? If they did not, all the pledges in the world would be of no use to them.

He would utter two warnings. There were such things as medical institutes and dispensaries—about 70 or 80 were already established—where men were engaged on a whole-time service, and those institutions were spreading. If they wanted to encourage them, get up a doctors' strike; that was the way to help them along. They were being run now at 4*s.* a head; under the Act it would be 6*s.*, and if the doctors refused to work the Act the working classes could not be without medical attendance, so medical institutes and dispensaries would swarm in the land. His second warning was this: It was with great difficulty that the Government succeeded in getting the safeguards in the Act. Friendly Society men present would know that the Government came pretty near a quarrel with the societies in order to protect the doctors. The Friendly Societies resented the safeguards as showing want of confidence in them. If the doctors threw over those safeguards, and if the old relations ensued, let them not forget the Government found the position difficult when facing societies with four or five million members. There would be 14 million members in the future. Would any Government face the risk of resuming those safeguards in the teeth of 14 million people, after the experience this Government had had with the doctors? If these people who were "egging" the doctors on—he did not say their leaders, they were generally persons outside, busybodies meddling for purely political purposes, who would not have done it unless they thought they could break down the Act by doing it—if these people succeeded, did they really think they would be able to make the Act unpopular? Quite the reverse. What was unpopular was taking these powers from Friendly Societies. There was nothing they wanted more than to have their powers restored and to have freedom of action. If as a result of a refusal to work the Act the insurance funds were handed over to the societies to deal with as they pleased, it would be hailed with joy by all the Friendly Societies.

He still believed the arrangements of the Act were the best, and he was prepared to work patiently through the temporary unpopularity associated even with the safeguards he had referred to, because he thought they were the best for the medical profession, and best for the working classes in the long run; but if impulsive, misinformed men lured on the medical profession for political reasons, let its members not send the bill to the Government, but to the men who had enticed them to their destruction.

PARLIAMENTARY INTELLIGENCE.

PARLIAMENT assembled on Feb. 14th. The first few days of the session in the House of Commons will be devoted to the debate on the Address, and it is expected that allusions will be made to the attitude of the medical profession on the Insurance Act. Indeed, on the opening day Mr. BONAR LAW, the Leader of the Opposition, made a reference to the "threats" of the Chancellor of the Exchequer. Attention was also drawn in the King's Speech to the International Opium Convention, the gist of which is contained in an article on p. 441 of this issue of THE LANCET.

Medical News.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Uhtoff, of Breslau, Dr. Hess, of Würzburg, and Dr. Axenfeld, of Freiburg, have all declined the chair of Ophthalmology in succession to Professor von Michel.—*Dijon:* Dr. Petitjean has been appointed Professor of Pathology in succession to Dr. Misset.—*Düsseldorf* (*Academy of Practical Medicine*): Dr. August Hoffmann, professor of medicine, and Dr. Arthur Schlossmann, professor of pædiatry, have been appointed Secretaries to the Academy.—*Göttingen:* Dr. A. Kantorowicz has been recognised as *privat-docent* of Odontology.—*Iurieff* (*Dorpat*): Dr. O. Rothberg has been recognised as *privat-docent* of Medicine.—*Königsberg:* Dr. Wilhelm Meisner has been recognised as *privat-docent* of Ophthalmology.—*Saratoff:* Dr. Bogolinboff, of Kazan, has been appointed Professor of Surgery.—*Vienna:* It is expected that the chair of Medicine now held by Dr. C. von Noorden will shortly be vacated, as the professor is going to take up his residence in Frankfort, where he will have the direction of a special clinic for diabetes which is now being erected.—*Würzburg:* Dr. Eugen Fischer, of Freiburg, has been offered the post of First Assistant in the Anatomical Institute.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—The annual dinner of this society was held at the Hotel Great Central on Feb. 8th, under the chairmanship of Mr. W. McAdam Eccles, the President. There was a good attendance of members and guests, and a most enjoyable evening was spent. After the loyal toasts had been honoured, Mr. J. G. Pardoe proposed the health of the Imperial Forces, and referred in eloquent terms to the debt owed by civilians to the defensive services of the Empire. This toast was responded to by Sir James Porter, Medical Director-General of the Navy, and Sir W. Launcelot Gubbins, Director-General of the Army Medical Service, who were both warmly received. At the invitation of the chairman Sir Philip Magnus, M.P., spoke a few words on the relations of the medical profession to the National Insurance Act. He said that the present public discussion of the medical aspects of the measure should have taken place long ago, before ever the Bill was introduced. If the profession had shown at an earlier stage the determination which it now showed the six cardinal points would have been incorporated in the Act. The £2 income-limit should have been insisted upon as the foremost demand of the profession, because it was essential that the area of contract practice should be limited. The profession must hold together and present a united front; it still held the fate of the scheme in its hands. Launching the Insurance Act without the doctors was like advertising the production of *Hamlet* without securing a performer for the central figure. It was not at all certain whether the Commissioners had the power to satisfy medical requirements, but the first duty of the profession was to ascertain whether this could be done. Medical men ought to coöperate in bringing the Act into operation, provided that their just terms could be secured. The health of the society was proposed by the chairman, who said that during the 30 years of its existence it had steadily grown in size and importance. Mr. Eccles referred to the value to the society of its close connexion with the West London Hospital and the Post-Graduate School. It now had 600 members, a flourishing journal, and an excellent programme of meetings. He announced that the Cavendish lecturer for the year was Professor Karl Pearson. He said that the society brought them all together at a cost per annum of 1*s.* less than they would receive for each person under the Insurance Act. Upon that matter, in spite of the insinuations of certain sections of the press, the general practitioner and the much-abused practitioner of Harley-street were at one. Mr. F. Lawrence, the senior member of the society and its president in 1884, in his reply traced the history of the society and its annual dinner from their small beginning in the early "eighties." Dr. S. D. Clippingdale, in a short humorous speech, welcomed the guests, including the representatives of kindred medical societies. Sir Henry Morris, President of the Royal Society of Medicine, was prevented by illness from attending and responding to this toast, but Dr. J. Mitchell Bruce,

President of the Medical Society of London, who replied jointly with Mr. Whitaker Thompson, Mayor of Kensington, and Dr. J. A. Macdonald, chairman of Council of the British Medical Association, regretted that the interest of the members of the Royal Society of Medicine was in some ways too sectional. This was shown in part by the poor response to the appeal for funds towards the new buildings shortly to be opened. Dr. Mitchell Bruce congratulated the West London Medico-Chirurgical Society on its firm hold upon the general practitioner, who alone could solve many of the most important questions in etiology and therapeutics; under the Insurance Act the general practitioner's opportunities in this direction would be curtailed, and his prospects of scientific advancement would be almost hopeless. The last item on the programme was the toast of "The Chairman," which was proposed by Professor Howard Marsh, Master of Downing College, in a few happy words. During the evening Mr. Watkin Mills and Miss Maguire gave some charming songs.

VACCINATION OFFICERS AND THEIR FEES.—The Wandsworth board of guardians at its meeting on Feb. 8th considered a letter from the vaccination officers drawing attention to the financial loss sustained by them in consequence of the working of the Vaccination Act and the Local Government Board Order, 1907. They asked the board either to increase their fees or grant them salaries, and also to make them gratuities for losses in past years. From a return presented to the board it appeared that in the Battersea district the average amount received in fees from 1903–07 was £219 6*s.* 2*d.*, average exemptions, 139; and in 1908–11 average fees £180 0*s.* 1*d.*, average exemptions, 616. Wandsworth district, 1903–07, average fees £104 3*s.* 3*d.*, average exemptions, 49; in 1908–11 average fees £98 4*s.* 7*d.*, average exemptions, 254. Putney district, 1903–07, average fees, £28 2*s.* 8*d.*, average exemptions, 121; 1908–11, average fees, £28 8*s.* 10*d.*, average exemptions, 47. No details were available for the Clapham district, but the remuneration in 1911 was £47. In the Streatham district, where the officer had resigned, the payment in 1911 was £99 15*s.* 1*d.*, but it was estimated that the fees would produce about £120 a year. The finance committee, who had considered the letter, stated that it appeared desirable that the vaccination officers should in future be paid by salary, and recommended that the stipend for Battersea should be £200 a year; Wandsworth and Clapham, £150; Streatham, £120; and Putney, £30. Lieutenant Sanders, R.N., in moving that the report be referred back, said that it was most extraordinary that in Wandsworth, where they had an increase in the population of 50,000, there should be a decrease in the vaccination fees. He did not object to the officers being paid salaries, but he objected to the suggestion made by the committee that the working of Mr. John Burns's Order was responsible for a diminished birth-rate. Mr. J. R. Archer seconded. Mr. G. B. Muter said that as the work was less the fees diminished, and consequently in striking at an average this should have been taken into account. He thought the salaries suggested were too excessive. If the board decided to grant the officers salaries there would not be the same inducement for them to press parents to get their children vaccinated. Mr. Archer: All the better for the children. Mr. P. Rees, the vice-chairman, said that the more exemptions the officers got the more work they got. Mrs. Cassidy, while inclined to pay the officers a salary, said that she was not agreeable to give them the large amounts proposed. If a ratepayer's business stopped he would not be expected to be relieved from the rates. The chairman (Canon Curtis) said that the finance committee went very carefully into this matter and the letter of the vaccination officers, along with the figures supplied. Through no fault of their own the salaries of these officers had decreased, and were likely further to decrease. They were engaged with the idea that they would have something approaching a fixed income, but that was now impossible. The committee thought that the best thing was to pay them a salary. In the case of Battersea the average fees received for the five years 1903–07 was over £200, and considering the decrease in the second period, they suggested £200 as a fair annual stipend. If the board were to pay these officers he thought they should be paid well. Mr. J. Wingfield said that as an antivaccinator he was glad to see that they were abolishing the pernicious system of payment by results. The board, by 17 votes to 4, adopted the committee's recommendation to pay the officers salaries, subject to the approval of the Local Government Board.

THE Cheshire county council has decided to advance the salary of its medical officer of health, Dr. Meredith Young, from £750 to £850 per annum, as from April 1st, and to follow this by three annual increments of £50 to a maximum of £1000.

UNIVERSITY OF CAMBRIDGE.—Dr. Jamieson B. Hurry (St. John's) has endowed a research studentship in physiology of the value of £100, tenable for one year and available every two years. It is suggested that the holder of the studentship shall be called the "Michael Foster research student," and the council has recommended that the first election shall be made in 1913.

CONGRESS OF PHYSIOTHERAPY, PARIS.—The Fourth Congress of Physiotherapy of French-speaking Physicians will be held at Paris on April 9th, 10th, and 11th. The subjects for discussion will be the following: Physical Agents in Chronic Rheumatism; Physical Agents in Obesity; and Physical Agents in Exophthalmic Goitre. The subjects of Acne, Angioma and Nævi, which have been withdrawn in view of the Congress of Dermatology to be held in Rome, will, nevertheless, receive a certain amount of attention. This Congress is organised by the delegates of the French Society of Electrotherapy and Radiology, the Society of Kinesitherapy, and the Society of Radiology of Paris. The President is M. le Professeur Bergonié (of the Société Française d'Electrothérapie), the treasurer is Dr. L. Delherm (2, rue de la Bienfaisance, Paris), and the secretary-general is Dr. A. Laquerrière of the same address. The subscriptions payable are 15 francs each for active members, the same amount for "membres adhérents" who do not take an active part, and 10 francs each for the wives or children of the members of the Congress.

UNIVERSITY OF LONDON.—University medals have been awarded on the results of the M.D. examination for internal and external students, December, 1911, as follows:—Branch I. (Medicine), Mr. Norman Claudius Lake, B.S., B.Sc. (Charing Cross Hospital); Branch IV. (Midwifery and Diseases of Women) Mr. William Henry Miller, B.S. (Guy's Hospital); Branch VI. (Tropical Medicine), Mr. Hugh Stannus Stannus (St. Thomas's Hospital and London School of Tropical Medicine). Dr. H. L. Eason has been appointed a member of the council for external students for the remainder of the period 1911–12 in place of Dr. Leonard Hill, resigned. Regulations have been adopted for the administration of the Medical Research Fund for which provision was made in the will of the late Dr. Charles Graham. The income of the fund, which will amount to about £1250 a year, will be devoted to aiding research in the School of Advanced Medical Studies connected with University College Hospital. A director of research will be appointed at a salary not exceeding £400 a year; there will be a scholarship in pathology of the value of £200 a year, tenable for two years; and provision is also made for the award of a gold medal for pathological research, for making grants to workers in the aboratories, and for defraying the expenditure on apparatus.

CHICHESTER INFIRMARY.—A year of satisfactory progress was reported at the annual meeting on Feb. 8th of the governors of Chichester Infirmary—in fact, for the first time for many years the income exceeded the expenditure by the sum of £72 5*s.* 1*d.* For the first time, also, all legacies received during the year, a matter of £311, instead of being placed to the general account and expended, had been placed to the reserve fund. The annual subscriptions rose during the year from £1194 to £1470, and the collections in boxes (470) from £66 to £267, an increase on the latter of no less a sum than £201. The fear lest curtailment of the work of the institution would follow if further subscriptions were not forthcoming has had effect, and the increased box collection shows how the institution is appreciated by those who must derive the greatest benefit from it. The number of in-patients during the year was 704 and of out-patients 2155, the latter being the largest number on record; while the number of major operations reached 506. The percentage of mortality was low, being 4 1 per cent. of the numbers treated, and, exclusive of patients admitted in a hopeless condition or dying within the 24 hours, 3·04 per cent., and of

those succumbing after operations 1·18 per cent. Regret was expressed that greater progress had not been made with the King Edward VII. reconstruction scheme, but the sum to be expended was large, and the difficulty of adapting an old building to the present stringent modern requirements great, so that the governors were determined to take time that they might obtain the best results. The financial position of the institution had improved, and the governors saw no reason why it should not continue to improve with an up-to-date building and the continued goodwill of the district, but there were still clouds which obscured the horizon—the National Insurance Act, the results of which none could foretell, and the debt on the general account. The governors paid a high compliment to the medical and nursing staffs.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

ADDISON, W. B., M.B., B.S. Cantab., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the St. Mary's (Scilly Isles) District of the county of Cornwall.

ALLNUTT, E. B., M.R.C.S., L.R.C.P. Lond., has been appointed Assistant House Surgeon at the West London Hospital.

ANDERSON, C. V., M.R.C.S., L.R.C.P. Lond., has been appointed Casualty Officer and Resident Anæsthetist at St. Thomas's Hospital.

BAZETT, H. C., M.B., B.Ch. Oxon., F.R.C.S. Eng., has been appointed Casualty Officer and Resident Anæsthetist at St. Thomas's Hospital.

BEADLES, J. N., M.B., B.S. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Cinderford District of the county of Gloucester.

BIRLEY, J. L., M.R.C.S., L.R.C.P. Lond., has been appointed Casualty Officer and Resident Anæsthetist at St. Thomas's Hospital.

BRANDON, G. N., M.R.C.S., L.R.C.P. Lond., has been appointed Resident House Surgeon at St. Thomas's Hospital.

BYRNE, J. A., L.M.S.S.A. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Youlgreave District of the county of Derby.

CHAVASSE, A. R., M.B., B.Ch. Oxon., M.R.C.S., L.R.C.P. Lond., has been appointed Resident House Physician at St. Thomas's Hospital.

EGAN, JOHN PATRICK, L.R.C.P. & S. Irel., L.M., has been appointed Assistant House Surgeon at the Taunton and Somerset Hospital.

FRY, H. J. B., M.B., B.Ch. Oxon., M.R.C.S., L.R.C.P. Lond., has been appointed Resident House Physician at St. Thomas's Hospital.

GARDNER, A. D., M.B., B.Ch. Oxon., M.R.C.S., L.R.C.P. Lond., has been appointed Casualty Officer and Resident Anæsthetist at St. Thomas's Hospital.

GRAINGER, J. P., L.R.C.P. & S. Irel., L.M., has been appointed Junior House Surgeon at the Croydon General Hospital.

HAMILTON, A. K., M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon at St. Thomas's Hospital.

HIGGINS, A. G., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Newent District of the county of Gloucester.

HUGHES, PERCY T., M.B., C.M. Edin., D.P.H., has been appointed Lecturer on Mental Diseases at the University of Birmingham.

HUMPHRYS, F. J., M.R.C.S., L.R.C.P. Lond., has been appointed Clinical Assistant to the Skin Department at St. Thomas's Hospital.

JOHNSON, A. C., B.C. Cantab., M.R.C.S., L.R.C.P. Lond., has been appointed Resident House Physician at St. Thomas's Hospital.

JONES, ERNEST LLOYD, M.D. Cantab., has been appointed Demonstrator in Medicine at the University of Cambridge.

LAIRD, W. B., M.R.C.S., L.R.C.P. Lond., has been appointed Casualty Officer and Resident Anæsthetist at St. Thomas's Hospital.

LAUDERDALE, E. M., M.R.C.S., L.R.C.P. Lond., has been appointed Senior Obstetric House Physician at St. Thomas's Hospital.

LOCK, N. F., B.A. Cantab., M.R.C.S., L.R.C.P. Lond., has been appointed Casualty Officer and Resident Anæsthetist at St. Thomas's Hospital.

MARSDEN, W. G., M.B., B.C. Cantab., M.R.C.S., L.R.C.P. Lond., has been appointed Resident House Surgeon at St. Thomas's Hospital.

MASSON, CHARLES ARMIT, M.B., Ch.B. Aberd., has been appointed Assistant Medical Officer at Coton Hill Hospital, Stafford.

MITCHINER, P. H., M.R.C.S., L.R.C.P. Lond., has been appointed Clinical Assistant to the Children's Surgical Department and to the Throat Department at St. Thomas's Hospital.

OAKDEN, W. M., M.R.C.S., L.R.C.P. Lond., has been appointed Resident House Surgeon at St. Thomas's Hospital.

PINTO-LEITE, HUBERT, M.R.C.S., L.R.C.P. Lond., has been appointed Second Anæsthetist to the Evelina Hospital for Children.

PONTON, JOHN ALFRED WILLIAM, M.B., B.Ch., B.A.O. Dub., has been appointed Medical Officer to the Ottery St. Mary (Devon) Cottage Hospital.

RIXON, C. H. L., M.R.C.S., L.R.C.P. Lond., has been appointed Casualty Assistant at St. Thomas's Hospital.

ROSS, W. D., M.R.C.S., L.R.C.P. Lond., has been appointed Resident House Physician at St. Thomas's Hospital.

ROUQUETTE, S. H., M.R.C.S., L.R.C.P. Lond., has been appointed Resident House Surgeon at St. Thomas's Hospital.

SALMOND, R. W. A., Ch.M., M.D. Aberd., D.P.H., has been appointed Surgeon-in-Charge of the X Ray Department at St. Mary's Hospital for Women and Children, Plaistow.

SKRIMSHIRE, F. R. B., M.R.C.S., L.R.C.P. Lond., has been appointed Ophthalmic House Surgeon at St. Thomas's Hospital.

SMITH, F. BATTINSON, M.R.C.S., L.R.C.P., has been appointed House Physician at the Warneford, Leamington, and South Warwickshire General Hospital, Leamington Spa.

TAYLOR, J. F., M.R.C.S., L.R.C.P. Lond., has been appointed Junior Obstetric House Physician at St. Thomas's Hospital.

TREHERNE, C. W., M.R.C.S., L.R.C.P. Lond., has been appointed Clinical Assistant to the Children's Medical Department at St. Thomas's Hospital.

VESSELOVSKY, V. C., M.R.C.S., L.R.C.P. Lond., has been appointed Casualty Assistant at St. Thomas's Hospital.

WATSON, GEORGE W., M.D. Lond., M.R.C.P. Lond., M.R.C.S., has been appointed Honorary Physician to the Leeds Association for the Prevention and Cure of Tuberculosis.

WEDGWOOD, W. B., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the King's Lynn (No. 2) District of the county of Norfolk.

WHORLOW, C. G., M.R.C.S., L.R.C.P. Lond., has been appointed Clinical Assistant to the Ear Department and to the Throat Department at St. Thomas's Hospital.

WIGMORE, J. B. A., M.R.C.S., L.R.C.P. Lond., has been appointed Clinical Assistant to the Children's Medical Department at St. Thomas's Hospital.

Vacancies.

For urther information regarding each vacancy reference should be made to the advertisement (see Index).

BANBURY, HORTON INFIRMARY.—House Surgeon. Salary £80 per annum, with board and residence.

BARROW-IN-FURNESS, NORTH LONSDALE HOSPITAL.—House Surgeon. Salary £100 per annum, with board and lodging.

BARRY URBAN DISTRICT COUNCIL.—School Medical Officer. Salary £400 per annum.

BIRMINGHAM AND MIDLAND EYE HOSPITAL.—Resident Surgical Officer. Salary £100 per annum, with apartments, board, and attendance.

BIRMINGHAM AND MIDLAND HOSPITAL FOR SKIN AND URINARY DISEASES.—Clinical Assistant. Salary at rate of 52 guineas per annum.

BIRMINGHAM UNIVERSITY.—Lecturer in Physiology. Salary £150 per annum.

BOMBAY, BARODA, AND CENTRAL INDIA RAILWAY.—Two Medical Officers. Salary Rs.500 per calendar month.

BRADFORD HOSPITAL AND WORKHOUSE.—Assistant Resident Medical Officer (female). Salary £130 per annum, with rations, apartments, and washing.

BRISTOL GENERAL HOSPITAL.—Senior House Surgeon. Salary £120 per annum, with board, residence, &c.

CAMBRIDGE, ADDENBROOKE'S HOSPITAL.—Second House Surgeon. Salary £80 per annum, with board, residence, and laundry.

CHARING CROSS HOSPITAL.—Physician.

CHARING CROSS HOSPITAL MEDICAL SCHOOL.—Lectureship in Hygiene and Public Health.

DERBY COUNTY ASYLUM, Mickleover.—Junior Assistant Medical Officer. Salary £120 per annum, with apartments, board, washing, and attendance.

DEWSBURY AND DISTRICT GENERAL INFIRMARY.—House Surgeon. Salary £120 per annum, with board, residence, and washing.

DUMFRIES AND GALLOWAY ROYAL INFIRMARY.—Assistant House Surgeon. Salary £55 per annum, with board and washing.

DUNDEE ROYAL INFIRMARY.—Non-resident Obstetric Assistant.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark, London, S.E.—House Physician for six months. Salary at rate of £75 per annum, with board, residence, and washing.

EXMINSTER, DEVON COUNTY ASYLUM.—Fourth Assistant Medical Officer. Salary £130 per annum.

HAMPSTEAD GENERAL AND NORTH-WEST LONDON HOSPITAL.—House Physician and House Surgeon, each for six months. Salaries at rate of £70 per annum, with board and residence.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.—Clinical Pathologist and Bacteriologist. Salary £200 per annum.

HOSPITAL FOR WOMEN, Soho-square, W.—Resident Medical Officer for six months. Salary at rate of £60 per annum.

INFANTS HOSPITAL, Vincent-square, Westminster.—Assistant Physician.

LARBERT, STIRLING DISTRICT ASYLUM.—Junior Assistant Medical Officer. Salary £130 per annum, with board, &c.

LEEDS GENERAL INFIRMARY.—Medical Tutor. Salary £125 per annum. Also Medical Registrar. Salary £25 per annum.

LIVERPOOL, DAVID LEWIS NORTHERN HOSPITAL.—Two House Physicians and Three House Surgeons, all for six months. Salaries at rate of £60 per annum, with residence and maintenance.

LIVERPOOL, ROYAL SOUTHERN HOSPITAL.—Two House Physicians and Three House Surgeons, all for six months. Salary at rate of £60 per annum, with board and residence.

MACCLESFIELD GENERAL INFIRMARY.—Junior House Surgeon. Salary £60 per annum, with board and residence.

MANCHESTER, ST. MARY'S HOSPITALS FOR WOMEN AND CHILDREN.—Two House Surgeons. Salary at rate of £50 per annum, with board and residence.

NEWCASTLE-UPON-TYNE UNION INFIRMARY AND WORKHOUSE.—Medical Superintendent. Salary at rate of £450 per annum.

NEW HOSPITAL FOR WOMEN.—Female Senior Assistants.

NOTTINGHAM GENERAL DISPENSARY.—Assistant Resident Surgeon, unmarried. Salary £160 per annum, with apartments, attendance, light, and fuel.

OXFORD, RADCLIFFE INFIRMARY AND COUNTY HOSPITAL.—House Surgeon and Casualty House Surgeon, unmarried, each for six months. Salaries at rate of £80 per annum, with board, &c.

ROYAL NAVAL MEDICAL SERVICE.—Fifteen Appointments.

RYDE, ROYAL ISLE OF WIGHT COUNTY HOSPITAL.—Resident House Surgeon, unmarried. Salary £100 per annum.

SALFORD ROYAL HOSPITAL.—Casualty House Surgeon. Salary at rate of £50 per annum, with board and residence.

SHEFFIELD UNIVERSITY.—Demonstrator in Experimental Physiology and Pharmacology. Salary £200 per annum.

SHREWSBURY, SALOP INFIRMARY (COUNTY HOSPITAL).—House Physician Salary at rate of £70 per annum, with board and apartments.

SOUTHAMPTON, ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.—Junior House Surgeon for six months. Salary at rate of £60 per annum, with rooms, board, and washing.

STOCKWELL TRAINING COLLEGE, Stockwell-road, S.W.—Medical Officer.

STOKE-ON-TRENT, NORTH STAFFORDSHIRE INFIRMARY, Hartshill.—House Surgeon. Salary £100 per annum, with apartments, board, and washing.

WEST AFRICAN MEDICAL STAFF.—Number of Appointments. Salary £400 per annum.

WESTERN GENERAL DISPENSARY, Marylebone-road, N.W.—Honorary Physician.

WEST LONDON HOSPITAL, Hammersmith-road, W.—Two House Physicians and Three House Surgeons for six months. Board, lodging, and laundry provided.

WEST RIDING OF YORKSHIRE COUNTY COUNCIL, Wakefield.—Medical Inspector. Salary £300 per annum.

WINCHESTER, ROYAL HAMPSHIRE COUNTY HOSPITAL.—House Surgeon. Salary £80 per annum.

WINDSOR, KING EDWARD VII HOSPITAL FOR WINDSOR, ETON, AND DISTRICT.—Senior House Surgeon. Salary £80 per annum, with residence, board, laundry, and attendance.

WINWICK, LANCASHIRE COUNTY ASYLUM, Warrington.—Assistant Medical Officer, unmarried. Salary £150 per annum, with board, apartments, and washing.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—Resident Medical Officer. Salary at rate of £100 per annum, with board, rooms, and laundry.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Castletown, in the county of Caithness; and at Lutterworth, in the county of Leicester.

Births, Marriages, and Deaths.

BIRTHS.

PEACOCK.—On Feb. 6th, at Penlu House, Craven Arms, Salop, the wife of W. H. Peacock, M.B., B.S., West African Medical Staff, of a daughter.

SWAN.—On Feb. 11th, at Wimpole-street, the wife of R. H. Jocelyn Swan, M.S. Lond., F.R.C.S., of a daughter.

MARRIAGES.

HORTON—BLACK.—On Feb. 10th, William Claude Horton, M.B., F.R.C.S., to Violet Muriel, younger daughter of the late William Black (Author) and Mrs. William Black, Paston House, Brighton.

WILLIAMS—POWELL.—On Feb. 10th, at Christ Church, High Harrogate, W. E. Rees Williams, Captain I.M.S., to Gertrude, second daughter of Charles A. Powell, of Oakwood Lodge, Harrogate.

DEATHS.

ALLCHIN.—On Feb. 8th, after a long illness, Sir William Henry Allchin, M.D., F.R.C.P., Physician Extraordinary to His Majesty the King, aged 65.

LISTER.—On Feb. 10th, at Walmer, the Right Hon. Lord Lister, O.M., F.R.S., in his 85th year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

LORD BROUGHAM AS HIS OWN PHYSICIAN.

To the Editor of THE LANCET.

SIR,—From '50 to '58 I was resident physician in the family of the last Lord Holland, he being in a very delicate state of health. I find in my diary of '55 the subjoined extract, which may interest you and your readers. It may be considered as a successful departure from the ordinary routine by an unqualified practitioner.

I am, Sir, yours faithfully,

Worthing, Jan. 19th, 1912. I. D. CHEPMELL.

EXTRACT FROM A MEDICAL DIARY OF 1855.

A constant visitor to Holland House during June and July was Lord Brougham, who was then in somewhat indifferent health, and glad to escape for a few nights from the heat and dust of London to enjoy the comparatively fresh air and cheerful surroundings of Holland House. On one occasion he arrived late in the evening, having contracted a bad cold attended with sore-throat and loss of voice. I advised him to go to bed at once, as he seemed feverish, and prescribed some appropriate remedy. With the first part of my recommendation he complied, but with the second he would have nothing to do, saying, "Don't you know that a man at 40 is either a fool or a physician, and sometimes both?" adding sharply, "How old are you, Doctor?" I was happy to be able to assure him, on wishing him good night, that I was only 26 years old.

Towards two o'clock in the morning I was awaked by a loud rapping at my door, and on opening found Lord B. standing in his nightshirt with an empty pitcher in his hand. In voice almost unintelligible from hoarseness he announced that he wanted a can of boiling water, some carbonate of soda, and a pot of currant jelly I thought he must be delirious, but as he was not to be put off by argument I thought best to pacify him by compliance with his strange request. At that time of night, everyone being fast asleep, the desiderata were not easily obtainable. Nevertheless, I set out on a foraging expedition; I woke up the old man of the kitchen, the old woman of the still-room, and returned with my spoils to the oddest of men upstairs, Lord B.

He was quite ready with his empty washing-jug, and proceeded to empty the pot of jelly into this receptacle, adding two large tablespoonfuls of soda, and filling up the jug with boiling water: the result, a foaming mixture of blood-red colour, and worthy of Macbeth's witches, he carried off in triumph to his room. At half-past six I awoke, and with a guilty sense of having neglected my patient I went and rapped at Lord B.'s door, first gently, then loudly, and receiving no answer stealthily opened it. On the floor was the jug empty, as was also the bed. The room was in great disorder, and the window wide open. I was really alarmed, and a painful sequence of thoughts ran through my mind—delirium, suicide, inquest! with a rider of temporary insanity, and culpable neglect on the part of attendant physician! I rushed to the window, and was relieved to find no trace of such a terrible disaster.

Returning to my room I dressed hastily, and running downstairs to the library found it untenanted. The floor was strewn with torn-up papers, and on one of the writing tables lay a pile of letters ready for post, all the work of my energetic patient! From a housemaid who was dusting the apartment I learnt that Lord B. "had been up since five, and was now gone out." I met his lordship at the breakfast table shortly afterwards and found him perfectly well, his strange remedy having worked wonders.

A BROKEN NECK IN COURT.

A REMARKABLE case came before His Honor Judge Mackarness, with whom was Dr. H. Nethersole Fletcher acting as medical assessor, at Lewes county court on Feb. 6th. A carter named Weller brought a request for arbitration under the Workmen's Compensation Act. On August 3rd, 1909, a horse which he was driving was frightened by a motor-car, and Weller was thrown out of the cart and seriously injured. He was taken to hospital, where it was found he had concussion and spinal injury, and had complete paralysis of the arms, legs, and muscles. He remained in hospital for 13 weeks and received full compensation, 10*s.* a week, until July 29th last, when it was reduced to 7*s.* 6*d.* Dr. W. A. Dow, who took X ray photographs of Weller's neck on Feb. 5th, produced the negative in court; it showed a distinct injury about level with the fifth vertebra and signs of fracture and displacement. Dr. Dow expressed the opinion that any sudden movement of the neck or any exertion might result in further damage to the spinal column, with serious and speedy consequences. This opinion was supported by two other medical witnesses, but dissented from by one who had examined him in July last, and who

thought that while no doubt the man had had a very serious injury and had made a miraculous recovery, there was nothing to prevent his taking light work. He did not agree with the other medical witnesses as to the danger of a sudden movement of the neck, having regard to the fact that the accident happened two and a half years ago. His honour, after consulting the medical assessor who had examined Weller, came to the conclusion that Weller was not capable of doing any light work and that the reduction should not be made, and awarded Weller 10*s.* a week, the arrears to be paid, with costs.

THE VAGRANCY PROBLEM IN SURREY.

WHEREAS the experience of Sussex in having adopted the way-ticket and bread-station system for dealing with the vagrancy problem is that there has been a reduction of 41 per cent. in the number of casuals in six years, it is not surprising to find that Surrey is now proposing to follow the same example. A conference called by the Surrey county council was held at Kingston on Feb. 8th, at which every board of guardians in the county was represented, and it was decided to recommend the boards of guardians in that county to take steps to establish the system as soon as possible. Surrey is evidently finding some truth in the statement made by Sussex guardians that by their action they are simply driving the tramping fraternity into Surrey. But inasmuch as the main object of the scheme is to differentiate between the genuine working man in search of employment and the confirmed tramp, and at the same time to show the public that proper provision is made for feeding the casuals so that there is no reason whatever for charitable people to give to beggars calling at the doors, it will not be completely successful until the system is universal throughout the country. Surrey's action, however, shows that the movement is spreading. The system is in vogue in Berkshire and in adjacent unions in the counties of Oxford and Buckingham, and in every case the decrease in the number of tramps has been followed by a decrease of offences against the law. An article on the Sussex system appeared in THE LANCET on Nov. 18th, 1911, p. 1447.

MEDICAL LITERATURE FOR MEDICAL MISSIONARIES.

To the Editor of THE LANCET.

SIR,—You were good enough rather more than a year ago to put in THE LANCET an appeal for medical literature for doctors working in the mission field. May I ask you to tell your readers that any copies of the current numbers of THE LANCET will be gratefully received and forwarded to the missionaries by Miss B. Gambier Parry, Bacton, Wokingham, Berks.—I am, Sir, yours faithfully,

J. ANDERSON ROBERTSON, M.A., M.B.,
Secretary, Medical Missions Department, S.P.G.

15, Tufton-street, Westminster, S.W., Jan. 31st, 1912.

THE CHLOROMETER.

THE Roborat Company, Limited, of 23, Cloth Fair, Aldersgate, London, E.C., have submitted to us a simple graduated glass instrument called the chlorometer, which is designed for the estimation of the chlorides in urine in clinical practice. The test is based upon the discharge of the blood-red colour of iron sulphocyanide by silver nitrate. In the presence of chlorides silver chloride is first formed, and as soon as the chlorides have been precipitated the red colour of the sulphocyanide begins to be discharged. The process is sufficiently accurate for most clinical purposes. It is carried out as follows. In ordinary circumstances the urine is diluted a tenth. The diluted urine is then poured into the tube up to the mark U; then a mixture of iron alum solution and dilute nitric acid (normal acid answers very well) to the mark I, followed by N/10 sulphocyanide of sodium solution to the mark T. A decinormal solution of silver nitrate is next added until the blood red colour of the sulphocyanide is discharged. The reading at the top of the mixed fluids gives at once the amount of chlorine present in milligrammes per cubic centimetre of urine. As an example, we took a 1 per cent. solution of common salt as representing a normal urine. This was diluted one-tenth with distilled water. The ultimate reading on the tube after carrying out the test in the manner just described was 6·5 milligrammes per cubic centimetre of original salt solution, which gives 1·07 per cent. of common salt found as against 1 per cent. calculated.

A VEGETARIAN DIET FOR AN INFANT.

A MEDICAL MAN has asked for assistance in drawing up a vegetable dietary for the twelve months' old daughter of a patient who, having become completely relieved of his rheumatism under a vegetarian diet, is desirous of bringing up his little daughter thereon, but is properly anxious that it should include all the elements necessary to growth and development. This is a matter on which it is difficult to speak with precision and authority, but any such dietary must include adequate variety without excessive quantity; adaptation to idiosyncrasies, habits, and familial peculiarities; an adequate proportion of hard foods to promote development of jaws and teeth; a limit of four meals daily, with three as the optimum. On these principles the following is suggested:—*Breakfast:* One cup of bread-and-milk, one finger of toast, with butter, home-made apple jelly, or honey. The toast should gradually be increased and the bread and-milk decreased as the teeth develop. *Dinner:* One potato, banana, or baked apple, with rice, macaroni, or other milk pudding. As the child gets older, bean pie, mock chicken cutlets, mock fish, or mock beef rissoles are substantial substitutes for the milk puddings. Details for their preparation may be obtained from "Hints towards Diet Reform," price 2*d.* (see THE LANCET, Feb. 10th, p. 409), and "Economical Dishes for Workers," price 1*d.*, both published by the National Food Reform Association, 178, St. Stephen's House, Westminster. *Tea:* The same as breakfast. Food taken before going to bed—a practice generally to be deprecated—should consist of a small cup of vegetable soup. Speaking generally, a child between one and two years of age requires less than one-third of the total quantity of food needed by a man at moderate work (Atwater). Many authorities who are in entire sympathy with vegetarian principles in their application to adults nevertheless recognise the value of animal proteids in building up the tissues of the growing child, and there is at times undoubtedly observable a want of energy and vigour in children brought up on a too rigid vegetarian diet.

A USEFUL "TOASTER."

WE have received from Messrs. Harrods, Limited, a specimen of a "toaster" which might be quite a useful adjunct to the sick-room. It consists of a plated metal frame on four legs, supporting a thin metal sheet and a square of wire gauze, beneath which is a spirit lamp whose wick can be adjusted to give a large or small flame by rotating a handle. By placing cut bread on the gauze excellent toast can be made in a few minutes, and in summer time the toaster can be used for keeping a dish warm or for heating milk.

M. G. (Bombay).—For the last three centuries, at any rate, it has been generally felt that the ordinary processes of the law form a better protection against such outrages.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced for March and April:—

March 7th–11th (Berlin).—Thirty-third Balneological Congress.
March 23rd–April 4th (London, Royal Agricultural Hall).—International Smoke Abatement Exhibition.
April 1st and 2nd (Milan).—Italian National Convention upon the Sexual Question.
" (London).—First Congress of Pure Food and Health Society of Great Britain.
" 1st–7th (Tunis).—Twenty-second Congress of French-speaking Alienists and Neurologists.
" 8th–13th (Rome).—Seventh International Congress of Dermatology and Syphilology.
" 8th–15th (Johannesburg).—Thirteenth South African Medical Congress.
" 9th–11th (Paris).—Congress of Physiotherapy for French-speaking Physicians.
" 9th (Berlin).—Eleventh Congress of the German Society for Orthopædic Surgery.
" 9th–13th (Giessen).—Congress on Study of Families, Inheritance, and Race Hygiene.
" 10th–13th (Berlin).—Forty-first Congress of the German Surgical Society.
" 14th (Berlin).—Eighth Congress of the German Röntgen Society.
" 14th–20th (Rome).—Seventh International Congress on Tuberculosis.
" 15th–18th (Wiesbaden).—Twenty-ninth German Congress for Internal Medicine.
" 21st–24th (Munich).—Twenty-sixth Meeting of the Anatomical Society.
" (London, Olympia).—Ideal Homes Exhibition.

The following journals, magazines, &c., have been received:—Ophthalmology, Archives Médecine et de Pharmacie Militaires, Annales de Gynécologie et d'Obstétrique, Monthly Cyclopædia and Medical Bulletin, Revue de Gynécologie, South African Medical Record, Archives of the Roentgen Ray, Dominion Medical Monthly, Journal of Tropical Medicine and Hygiene, Annali di Medicina Navale e Coloniale, Edinburgh Medical Journal, Tuberculosis, Review of Neurology and Psychiatry, La Clinica Castellana, Transvaal Medical Journal, Bulletin of the City of New York Lying-in Hospital, Archives Générales de Médecine, Indian Medical Gazette, Archiv für Experimentelle Pathologie und Pharmakologie, Dublin Journal of Medical Science, Sleeping Sickness Bureau Bulletin, Journal of Pathology and Bacteriology, North of England Clinical Journal, Canadian Medical Association Journal, Local Government Review, &c.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. temporary address during building of new house).

TUESDAY.

THERAPEUTICAL AND PHARMACOLOGICAL SECTION (Hon. Secretaries—H. Charles Cameron, H. H. Dale): at 4.30 P.M.

Discussion

On the Tuberculin Treatment of Pulmonary Tuberculosis (opened by Dr. Arthur Latham).

The following will take part in the Discussion:—Dr. Nathan Raw, Dr. W. d'Este Emery, Dr. A. C. Inman, Dr. S. V. Pearson, Dr. J. W. Linnell, Dr. J. J. Perkins, Dr. W. H. Wynn, Dr. D. Lawson, Dr. Paul Mathews, Dr. G. A. Crace-Calvert.

The DISCUSSION will be continued on the following day, Wednesday, Feb. 21st, at 4.30 P.M.

PATHOLOGICAL SECTION (Hon. Secretaries—J. C. G. Ledingham, A. E. Boycott): at 8.30 P.M.

Prof. Beattie and Dr. A. J. Hall: (1) A New Method of Mounting Museum Specimens; (2) Demonstration of Specimens of Neurofibromatosis and Multiple Embolic Aneurysms of the Pulmonary Artery.

Dr. J. A. Arkwright: Variation in Colonies of *B. diphtheriæ*.

Dr. Hort and Dr. Penfold: Salvarsan Fever and its Relation to Other Types of Injection Fever.

Dr. Bayon: Animal Experiments in connexion with *B. lepræ*.

FRIDAY.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN (Hon. Secretaries—T. R. Whipham, H. S. Clogg, Percy G. Lewis), at 11, Chandos-street, W.: at 4.30 P.M.

Cases:

Dr. R. Hutchison: (1) Paralysis of the Muscles of the Neck (? Anterior Poliomyelitis); (2) Hysterical Vomiting followed by Achylia and Infantilism; (3) Fibroid Lung with a Large Cavity at the Apex.

Dr. H. Thursfield: Eruption of Green Teeth in a Case of Prolonged Jaundice.

Dr. F. Langmead: Bile-stained Teeth.

Dr. James Taylor: Athetoid Movements.

Dr. L. Guthrie: Transposition of the Viscera.

Dr. T. R. Whipham: Arthritis of the Shoulder and Hip (? Tuberculous).

EPIDEMIOLOGICAL SECTION (Hon. Secretaries—W. H. Hamer, G. S. Buchanan): at 8.30 P.M.

Paper:

Dr. Reginald Dudfield: Summer Diarrhœa in 1911.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—9 P.M., Dr. A. E. Garrod: Glycosuria. (Lettsomian Lecture II.)

LONDON DERMATOLOGICAL SOCIETY, 49, Leicester-square, W.C.

TUESDAY.—4.30 P.M., Demonstration of Clinical Cases. Adjourned Discussion on Dr. J. L. Bunch's paper on Prurigo and Itching Diseases of the Skin.

MEDICO-LEGAL SOCIETY, 11, Chandos-street, Cavendish-square, W.

TUESDAY.—8.30 P.M., Mr. G. Jones: Defects in the Organisation of the Medical Profession.

CHELSEA CLINICAL SOCIETY, St. George's Hospital Medical School, S.W.

TUESDAY.—8.30 P.M., Dr. Hyslop: The Intercranial Mechanism in Health and Disease.

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION, 11, Chandos-street, Cavendish-square, W.

THURSDAY.—4.30 P.M., General Meeting. Dr. J. G. Forbes: Pollution of Swimming Baths.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. J. Galloway: Clinique (Skin). 5.15 P.M. Lecture:—Mr. P. M. Yearsley: The Nasopharynx and its Relation to other Regions.

TUESDAY.—4 P.M., Dr. J. Collier: Clinique (Medical). 5.15 P.M., Lecture:—Dr. L. Guthrie: Hysteria in Childhood.

WEDNESDAY.—4 P.M., Mr. H. J. Paterson: Clinique (Surgical). 5.15 P.M., Lecture:—Mr. W. Arbuthnot Lane: Chronic Intestinal Stasis.

THURSDAY.—4 P.M., Mr. E. Corner: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. D. Drummond (Newcastle): Is it a Case for Operation? A Problem in Diagnosis.

FRIDAY.—4 P.M., Dr. S. Stephenson: Clinique (Eye).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 10.30 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12 noon, Dr. Bernstein: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Dunn: The Clinical Uses of Prisms.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 11 A.M., Mr. Etherington-Smith: Demonstration of Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. S. Taylor: Intestinal Ogstruction.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 10.30 A.M., Surgical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Simson: Diseases of Women. 5 P.M., Lecture:—Dr. Beddard: Practical Medicine. (Lecture IV.)

THURSDAY.—10 A.M., Dr. Simson: Gynæcological Demonstration. 12.15 P.M., Lecture:—Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture: Dr. R. H. Cole: Hypochondriasis.

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 12.15 P.M., Lecture:—Dr. Pritchard: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Simson: Extra-uterine Gestation.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. Bishop Harman: Diseases of the Eye. 10.30 A.M., Medical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10.30 A.M., Surgical Out-patient (Mr. B. Gillespie). 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Nose, Throat, and Ear (Mr. H. D. Gillies). 3 P.M., Clinical Pathology and Pathological Demonstration (Dr. W. H. Duncan).

TUESDAY.—Clinic; 2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld).; Surgical (Mr. Howell Evans); Gynæcological (Dr. A. E. Giles). 3.30 P.M., Medical In-patient (Dr. A. J. Whiting). 4.30 P.M., Lecture:—Dr. G. N. Meachen: The Treatment of Various Types of Eczema.

WEDNESDAY.—Clinics:—2 P.M., Throat Operations (Mr. Gillies). 2.30 P.M., Children's Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen): Eye (Mr. R. P. Brooks). 3 P.M., X Rays (Mr. W. Steuart); Clinical Pathology and Pathological Demonstration (Dr. W. H. Duncan). 5.30 P.M., Eye Operations (Mr. Brooks).

THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 P.M., Medical In-patient (Dr. G. P. Chappell). 4.30 P.M., Demonstration:—Dr. T. R. Whipham: Selected Cases of Children's Diseases.

FRIDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Surgical (Mr. B. Gillespie); Eye (Mr. R. P. Brooks). 3 P.M., Medical In-patient (Dr. R. M. Leslie); Clinical Pathology and Pathological Demonstration (Dr. W. H. Duncan).

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4.30 P.M., Mr. R. Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

TUESDAY.—2 P.M., Operations. 3.15 P.M., Dr. R. Wells: Medicine. 2.15 P.M., Mr. R. Carling: Surgery. 4.15 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye. 5 P.M., Special Lecture:—Mr. McGavin: Fractures.

THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 4.30 P.M., Special Lecture:—Dr. Lister: Pneumonia in Children.

FRIDAY.—2 P.M., Operations. 2.15 P.M., Sir J. Rose Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin. 2.15 P.M., Special Lecture:—Sir John Bradford: Ascites.

SATURDAY.—10 A.M., Radiography. 11 A.M., Dr. A. Davies: Pathological Demonstration. 2 P.M., Operations. Out-patient Demonstration:—10 A.M., Surgical and Medical. 11 A.M., Eye.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

THURSDAY.—4 P.M., Lecture:—Dr. Batten: Clinical Cases in the Ward.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC. Queen-square, Bloomsbury, W.C.

TUESDAY.—3.30 P.M., Clinical Lecture:—Dr. J. Taylor: Hemiplegia.

FRIDAY.—3.30 P.M., Clinical Lecture:—Dr. J. Taylor: Tabes Dorsalis.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.

TUESDAY.—6 P.M., Mr. W. Hampson: X Rays. Other Skin Affections.

THURSDAY.—6 P.M., Chesterfield Lecture:—Dr. M. Dockrell: The Solution of the Confusion between Pityriasis Rubra Pilaris and Lichen, and the Treatment of Each.

UNIVERSITY OF LONDON (UNIVERSITY COLLEGE), The Francis Galton Laboratory for National Eugenics.

TUESDAY.—8.30 P.M., Dr. M. Greenwood: Infantile Mortality in Relation to Administrative Control. (Lecture IV.)

ANCOATS HOSPITAL, Manchester.

THURSDAY.—4.15 P.M., Dr. C. H. Melland: Spasmodic Respiratory Affections. (Post-Graduate Clinic.)

MANCHESTER ROYAL INFIRMARY.

TUESDAY.—4.30 P.M., Dr. C. Moore: Some Conditions which may Simulate Disease of the Stomach.

FRIDAY.—4.30 P.M., Mr. C. Roberts: Tumours of the Breast.

SALFORD ROYAL HOSPITAL.

THURSDAY.—4.30 P.M., Mr. J. B. Macalpine: Swellings in the Neck (Post-Graduate Course).

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (19th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), Central London Throat and Ear (Minor 9 A.M., Major 2 P.M.).

TUESDAY (20th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London, (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.). Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.), Royal National Orthopædic (9.30 A.M. and 4 P.M.).

WEDNESDAY (21st).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's 2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

THURSDAY (22nd).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal National Orthopædic (9 A.M. and 3.30 P.M.), Royal Ear (2 P.M.), Children Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

FRIDAY (23rd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Royal National Orthopædic (3.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.)., Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

SATURDAY (24th).—Royal Free (9A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.), Hospital operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

The Index and Title-page to Vol. II. of 1911 were given in THE LANCET of Dec. 30th, 1911.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1911 are now ready. Bound in cloth, gilt lettered, price 16*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

Lettsomian Lectures
ON
GLYCOSURIA.

Delivered before the Medical Society of London.

BY ARCHIBALD E. GARROD, D.M., M.A. OXON., F.R.C.P. LOND., F.R.S.,

PHYSICIAN TO, AND LECTURER CHEMICAL PATHOLOGY AT, ST. BARTHOLOMEW'S HOSPITAL; PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN.

LECTURE I.

Delivered on Feb. 5th, 1912.

MR. PRESIDENT AND GENTLEMEN,—When entrusted with the delivery of a course of lectures founded to perpetuate the memory of a distinguished man of the past, one would wish to choose a subject in which he took some special interest. This satisfaction is denied to me this evening, for I can find nothing to indicate that among the diverse subjects which occupied the many-sided mind of Dr. Lettsom, the study of the renal excretion held any prominent place. Indeed, the only one of his writings with which I am acquainted, which relates to the matter, is a counterblast to the arrogant pretensions of a class of empirics who claimed to diagnose diseases by a mere inspection of the patients' urine.

Nevertheless, when I was honoured by the council of the Medical Society with the invitation to deliver the Lettsomian lectures of the current year—an honour which I appreciate most highly, and for which I beg to return my sincere thanks—I was emboldened to take glycosuria as my theme when I found that the first Lettsomian lecturer of all, Dr. Owen Rees, had treated of "Some of the Pathological Conditions of the Urine," and that the lecturer of the year 1860, Dr. Pavy, whose decease at a ripe old age we have so recently deplored, gave some of the first fruits of his investigations of diabetes, a research which was extended over more than 50 years of a long and honoured life. My subject was evidently beyond reproach, whatever the defects in my presentation of it.

HISTORICAL SKETCH.

When we turn to the writings of past centuries for light upon the growth of our knowledge of glycosuria, we find that diabetes occupies a peculiar position as a malady which was recognised by, and described from, its other symptoms, centuries prior to the discovery of its cardinal sign. The clinical picture of a disease characterised by thirst, polyuria, and loss of flesh was drawn at the beginning of the Christian era by Celsus and others, and the name "diabetes" was used to designate it in the writings of Aretæus; but although it would appear that sugary urine was recognised in India at a very early date the real foundation of the study of glycosuria was laid by that great physician Thomas Willis, whose fame rests mainly upon his work on the anatomy of the brain, and whose name is immortalised in that of the arterial anastomosis, which he was the first to describe.

The following passage, which bears the stamp of original observation, is contained, in Latin form, in the "Pharmaceutice Rationalis," the last work of Willis, published in 1674, the year before his death:—

> But the statements of many authors, that the liquid imbibed is excreted little, if at all, changed, is very far from the truth; for in every case which I have met with, and I believe that this holds true for all cases, the urine has differed greatly from the imbibed fluids, as also from any humour which is wont to be generated in our bodies, in that it is remarkably sweet, like a solution of honey or sugar.[1]

Richard Morton,[2] writing in 1698, was evidently well acquainted with this property of diabetic urine, which he describes as having lost its saltness, and as being sweet like honey, as if from a copious admixture of fresh chyle. However, the statements of the English physicians seem to have met with little acceptance on the continent, where they were questioned or denied in not a few quarters, and it was not until a century had elapsed since Willis wrote, that the next important step was made, and there was published a paper by Matthew Dobson,[3] of Liverpool, in 1776, which may justly be described as epoch-making.

Dobson obtained the sugar from diabetic urine by evaporation, as a solid if impure mass; showed that such urine undergoes vinous and acetic fermentation, and detected the sweetness of the blood serum of a diabetic patient, from which he concluded that the sugar was excreted from the blood and not formed in the kidneys. If Willis discovered, or re-discovered glycosuria, to Matthew Dobson must be assigned the credit of having discovered hyperglycæmia. We may indeed claim for him the discovery of acetonuria also, for he speaks of the sweetish odour of diabetic urine, which can hardly have been due to anything but acetone.

We may well be proud of the past achievements of our countrymen in this field, for during the seventeenth and eighteenth centuries it was by British observers that all the chief advances in the study of diabetes were made, culminating in the introduction of the dietetic treatment of the malady by John Rollo[4] in 1796. It was a Frenchman, Chevreul, who proved, in 1807, the identity of the sugar present in diabetic urine with glucose or grape sugar.

Obviously the methods in use by the early investigators—taste, evaporation, and the like—can only have served to demonstrate the presence of large quantities of sugar, such as are excreted in the worst cases of diabetes, and the detection of the slighter forms of glycosuria can hardly have been possible, save by fermentation, prior to the introduction of Trommer's test[5] in 1841, of Moore's test[6] in 1844, and of Fehling's quantitative method[7] in 1849.

So it came about that our knowledge of glycosuria came through diabetes, and this provenance has profoundly influenced, and still influences, our ideas concerning it. We do not always realise sufficiently that our conceptions of any subject are shaped, not merely by the knowledge of it which we possess, but also by the manner in which that knowledge has been gained. It will be one of my aims to show, in these lectures, that we are more likely to obtain a just conception of both if we approach the study of diabetes through that of glycosuria.

Medical science is becoming hide-bound by an obsolescent system of classification of diseases, and by an inadequate terminology. The time-honoured classification, which was based upon clinical observation, aided by morbid anatomy, is giving place to one which has its foundations in bacteriology and an ampler pathology. The transition from old to new must needs be gradual, for whilst we are able to realise the imperfections of the older scheme, the knowledge requisite for the completion of the new scheme is still lacking. There are not a few diseases the fundamental nature of which is still wholly obscure.

Our terminology does not suffice for the expression of ideas which are rapidly coming into prominence, but which had no place in the older medicine. We recognise the fact that the same clinical picture may have its origin in a number of different pathological events, and the present-day use of such terms as "syndrome," "symptom-complex," and "morbid entity," bears witness to the need of new designations.

In some instances a clinical syndrome, such as those which we associate with scarlet fever and measles, affords evidence of the working of some definite and specific morbid process, due to the growth in the body of a specific micro-organism, and in such cases the syndrome is coextensive with the underlying disease. Other syndromes have their aspects determined by the seat, rather than by the nature, of the ground-lesion, as, for example, the meningitis syndrome (to which German physicians apply the term meningismus); and, seeing that different micro-organisms tend to attack different parts of the cerebro-spinal membranes, the grouping of symptoms may serve to reveal, or to lend strong probability to the double diagnosis of the nature of the infective agent and the region which is attacked. In yet other syndromes the grouped symptoms are, for the most part, dependent upon one primary symptom, and, given a morbid process which gives rise to that symptom, the others will, sooner or later, be added to it.

It is to a symptom-complex of this last kind that we are

[6] THE LANCET, 1844, vol. i., p. 751.
[7] Annalen der Chemie und Pharmakologie, 1849, Band lxxii., p. 106.

accustomed to give the name of diabetes mellitus; but it has long been recognised that cases of diabetes differ very widely in their course and outlook, and evidence is accumulating that diabetes is no definite circumscribed disease, but that the disturbance of carbohydrate metabolism which leads to accumulation of sugar in the blood, and so to glycosuria, has its origin in a variety of different causes.

DEFINITION AND DIAGNOSIS OF DIABETES.

No definition of diabetes which has yet been proposed meets all requirements, and this is what may be expected if the view just expressed be correct. One cannot accurately define what is essentially indefinite. In many cases of diabetes, glycosuria is for a time, and sometimes for a long time, the only morbid symptom, and is not infrequently detected at an examination for life insurance of a man who believes himself to be in excellent health. It is clear, then, that the presence of associated symptoms, such as thirst, polyuria, and loss of flesh, cannot enter into our definition. Persistence of the glycosuria is perhaps the criterion most often set up; but this is unsatisfactory, seeing that there is good reason for believing that recovery from diabetes occasionally occurs. The definition suggested by Naunyn that a patient who passes sugar after the free taking of starch is virtually a diabetic is perhaps the best, but as I hope to show later on, it is probable that the difference between such a person and one who only acquires glycosuria after a dose of cane sugar or glucose considerably less than is required to cause excretion of sugar by a normal individual is rather one of degree than of kind.

It is possible that the error of metabolism which leads to glycosuria is not identical in all cases, but that in one case the chief part may be played by increased formation and mobilisation of sugar in the organism, and in another impaired destruction may play the chief part. However, I do not propose to enter in these lectures upon any discussion of the many and difficult questions which the chemical pathology of glycosuria presents, but rather to deal with those aspects of the subject which are more purely clinical.

The Diagnosis of Glycosuria.

There is no urinary anomaly of which we should know more than of glycosuria, for thousands of specimens of urine are being tested for sugar every day, in the course of the routine examination of hospital and private patients, and of candidates for insurance. Only for albumin is as persistent an outlook kept. Yet when we turn to what has been written upon the subject we find that many recorded observations, which would otherwise be of great value and interest, are vitiated by the absence of conclusive evidence that the abnormal substance excreted in the urine is really glucose.

A reducing substance in urine which responds to the tests usually relied upon is not necessarily a sugar; and other sugars besides glucose are met with in urine. The development of a greenish opacity, which may appear only when a mixture of urine and Fehling's solution has been boiled for some time, or as it cools, may indicate the presence of glucose in small amount, but that it does so must not be assumed without further proof. Certain nitrogenous constituents of normal urine have some reducing power, and salicyluric acid, which is present in the urine of patients taking salicylates, causes such a reduction. On the other hand, an orange precipitate, formed when hot urine is mixed with hot Fehling's solution without re-boiling, affords almost conclusive evidence of the presence of a hexose monosaccharid, such as glucose or lævulose.

An orange precipitate, obtained on boiling, is sometimes due to the presence of a compound glycuronate. Glycuronic acid is closely allied to the sugars, but its presence is in no way indicative of a disorder of carbohydrate metabolism, but of the calling into play of one of the protective mechanisms, by means [of which the organism is enabled to avert from itself damage from chemical poisons introduced by the mouth, or toxic substances formed in the alimentary canal. The noxious substance is combined with glycuronic acid, and so excreted, just as benzoic acid is combined with glycocoll and excreted as hippuric acid. Hence the appearance of glycuronic acid in the urine indicates merely the need of dealing with such a poison.

Homogentisic acid, the aromatic acid which is excreted by those who exhibit the very rare, and usually congenital, error of protein metabolism known as alkaptonuria, is a powerful reducing agent; and alkaptonurics have sometimes been refused for insurance on this account. However, the other properties of alkapton urine are so striking as to render the diagnosis easy to anyone acquainted with these properties, which include darkening on standing or addition of alkalies, and the staining of garments, as by a photographic developer.

Sugars in Urine other than Glucose.

Of the sugars, other than glucose, which are met with in urine, lactose, lævulose, and the pentose sugar arabinose are the most important; whereas maltose, isomaltose, galactose, and the heptose recently described by Rosenberger [8] as present in a single case, have as yet little more than academic interest. A term is certainly needed to designate the excretion in urine of sugars generally, and this need is supplied by the word "mellituria," which has been somewhat widely employed of recent years by German medical writers.

Lactose.

After glycosuria, lactosuria is the commonest variety of mellituria, but it is only met with in certain definite circumstances, in the absence of which it may be excluded.

Lactose is sometimes excreted by women during the last months of pregnancy, but much more often and in larger quantities during lactation, and especially when, for any reason, nursing has suddenly been arrested. It may also be found occasionally in the urine of breast-fed infants or of those to whose bottle-food this sugar has been added. J. Grosz,[9] who made a careful study of the subject, failed to find lactose in the urine of healthy infants at the breast, but observed conspicuous reduction by the urine of such infants when suffering from gastro-intestinal disturbances. Langstein and Steinitz [10] proved, by methods which allow of no doubt, that the sugar excreted in such circumstances is really lactose, with an occasional admixture of galactose, which is one of the components of this disaccharid. In one case the bulk of the urinary sugar was galactose.

It is obvious that lactosuria has no connexion with glycosuria, and that further discussion of it will throw no light upon the problems with which we are concerned at present.

Pentose.

The same may be said of pentosuria, the symptom of a rare anomaly of metabolism which is probably harmless, but as it is easily mistaken for persistent glycosuria and has, in not a few instances, been treated as such by dietary restrictions which are very irksome, if not actually detrimental to the patient, it is clearly of great importance that it should be correctly diagnosed when met with.

The pentose excreted belongs to a wholly distinct class of sugars from glucose, its molecule being built up upon a chain of only five carbon atoms, and much obscurity still surrounds the origin of the pentose of urine, which is always arabinose, and almost always in the optically inactive or racemic form. This much appears certain—namely, that the metabolic error which underlies pentosuria is of a wholly different nature from that which brings about the excretion of hexose sugars.

Lævulose.

With lævulosuria the case is different, for glucose and lævulose sometimes occur together in the urine, so that there would appear to be some connexion between them.

Lævulose has been detected in small amounts in the urine of not a few diabetic patients, in association with much larger quantities of glucose. In other cases the proportion of lævulose is so much greater that the optical effect of the glucose is neutralised to no slight extent, and is occasionally balanced or over-balanced. For this condition the name of mixed mellituria has been suggested.

In almost all the recorded cases of this kind the exclusion of carbohydrates from the diet has brought about the disappearance of both sugars from the urine, and in some cases it has been found that when lævulose was taken by the mouth, even in doses calculated to overstep the tolerance of normal persons, no increase of the urinary lævulose has resulted.

Otto Neubauer [11] has described an example in which,

[8] Deutches Archiv für Klinische Medizin, 1907, Band lxxxviii., Zeitschrift für Physiologische Chemie, 1906, Band xlix., p. 202.
[9] Jahrbuch für Kinderheilkunde, 1892, N.F., Band xxxiv., p. 83.
[10] Hofmeister's Beiträge zur Chemischen Physiologie und Pathologie, 1905, Band vii., p. 575.
[11] Münchener Medizinische Wochenschrift, 1905, Band lii., p. 1525.

although a large dose of lævulose caused no increased output of that sugar, the administration of glucose brought about an increase of both glucose and lævulose in the urine. In some other cases as large a dose as 100 grammes of glucose has caused no increased excretion of either sugar. We must assume that, in Neubauer's case, glucose was in part converted into lævulose and excreted as such.

In a further group of cases of what may be styled pure lævulosuria, the excretion of lævulose is arrested by the removal of lævulose itself and saccharose, of which it is a constituent, from the diet, whereas glucose and starchy foods can be taken with impunity. Even inulin, a polysaccharid related to lævulose as starch is to glucose, fails to excite lævulosuria in such cases. In one case, for the most thorough investigation of which Otto Neubauer is again to be thanked, when the urine was freed from lævulose by dietary any dose of that sugar, however small, excited lævulosuria, and whatever the dose given, whether as little as 3·8 grammes, or as large as 50 grammes, practically the same fraction of it reappeared unchanged in the urine—namely, 15–17 per cent.

The whole subject of lævulosuria calls for much further investigation, but, seeing that what is needed is multiplication of observations of individual cases, and that such cases are extremely rare, progress must needs be slow.

Diagnostic Methods.

The occurrence of reduction when the hot urine is mixed with hot Fehling's solution without re-boiling indicates, as I have already mentioned, the presence of glucose or lævulose or both, but it does not serve to distinguish between them.

With lactose, which is a disaccharid of glucose and galactose, reduction is less prompt than with monosaccharids, and does not occur until the mixture is boiled. With pentose, also, the reduction occurs only after boiling—it may be only after somewhat prolonged boiling, and usually with remarkable suddenness. The quantity of arabinose excreted in cases of pentosuria is not large, and a pea-green rather than an orange opacity is usually observed.

In a urine which responds to Trommer's or Fehling's tests dextro-rotation of the polarised ray indicates the presence of glucose or lactose. The dextro-rotation may be conspicuously less than is to be expected from the reducing power, owing to the presence of a lævo-rotatory substance such as lævulose or β-oxybutyric acid, of which the latter is a common constituent of diabetic urines, and often an abundant constituent. Urine containing an evenly balanced admixture of dextrose and lævulose may be optically inactive. A lævo-rotatory urine, which reduces copper reagents, may contain lævulose, either alone or with a lesser quantity of glucose. Again, the compound glycuronates are lævo-rotatory, whereas glycuronic acid itself is dextro-rotatory. When, therefore, a urine which contains a compound glycuronate is boiled with hydrochloric acid, so as to set free glycuronic acid, its original lævo-rotation gives place to a dextro-rotation.

In all cases of pentosuria hitherto examined, with one or two exceptions, arabinose has been excreted in the racemic form, and the urine has been optically inactive. Nor do alkapton urines exert any effect on the polarised ray.

The fermentation test lends valuable aid. Dextrose and lævulose are fermented by yeast, whereas lactose is not so fermented within the 24 hours allowed for the test—that is to say, not until it has been split into its monosaccharid constituents. Arabinose is not fermented by yeast, and the glycuronates and homogentisic acid do not respond to this test.

The deposition of a crystalline osazone, on application of the phenyl-hydrazine test, indicates the presence of glucose, lævulose, or arabinose. Glucose and lævulose yield the same osazone, which melts, when pure, at 206° C., and this test affords no distinction between them.

The pentosazone melts at a much lower temperature, 150°–160° C. Lactose forms an osazone which melts at 200° C., but as it is much more readily soluble, and the quantities of lactose met with in urine are not large, it does not crystallise out from the dilute solution, even on cooling. Glycuronic acid, also, forms a crystalline compound with phenyl-hydrazine, but the compound glycuronates do not do this, and urines which contain them do not respond, therefore, to the phenyl-hydrazine test.

Lævulose forms a special compound with methyl phenyl-hydrazine, which melts at 153° C., and which serves for its differentiation from glucose, which does not yield an osazone with this base. Special tests, such as Rubner's for lactose, Seliwanoff's for lævulose, and the phloroglucin and orcin tests for arabinose and glycuronic acid, may also be employed.

The above summary will suffice to emphasise the importance of making sure, in any case which may serve as a basis of conclusions as to the occurrences, causation, or temporary character of a glycosuria, that the reducing substance in the urine is actually a sugar, and, if a sugar, glucose.

To ensure certainty, evidence should be forthcoming that the urine in question contains a dextro-rotatory reducing substance, fermented by yeast, and which yields an osazone of the correct crystalline form, and which melts, before re-crystallisation, at a point slightly above 200° C.

THE CLASSIFICATION OF THE VARIETIES OF GLYCOSURIA.

There are few symptoms in the whole category of morbid manifestations which own so many distinct causes as does glycosuria, and not one which is so uncertain, and apparently so capricious, in its appearance when its several causes are at work in the human organism. Even when the pancreas, the organ which, above all others, appears to be most intimately concerned with the metabolism of carbohydrates, is itself the seat of disease, glycosuria is only occasionally observed. In some of the gravest forms of pancreatic disease this symptom is rare.

In the following list I have collected together a large number of the known causes of glycosuria in man, but I am not prepared to contend that the list includes all the conditions in connexion with which excretion of sugar has been observed. Some varieties which have only been observed in the course of experiments upon animals have been intentionally omitted.

Toxic.—Administration of: Morphine, atropine, strychnine, curare, amyl nitrite, copaiba, phosphorus, perchloride of mercury, uranium salts, phloridzin, acetone. Anæsthetics: Chloroform, ether, nitrous ether. Poisoning by coal gas, carbon monoxide. Alcohol, especially in champagne and beer. Thyroid extract, adrenaline.
Asphyxia—i.e., accumulation of carbon dioxide in respired air.
Cold immersion (e.g., attempted suicide by drowning).
Inanition (vagabond glycosuria).
Psychic strain or shock.
Diseases of the nervous system.—Apoplexy, convulsions, traumatism, cerebral tumours, meningitis (meningococcal and tubercular), syphilitic affections of the brain, general paralysis of the insane, paralysis agitans, tabes.
Acute fevers.—Pneumonia, scarlet fever, measles, mumps, variola, malarial fevers, phlegmonous diseases.
Diseases of the liver.—Cirrhosis, cholelithiasis.
Diseases of the pancreas.—Hæmorrhagic pancreatitis, necrosis, carcinoma, fibrosis, pancreatitis of mumps, catarrhal pancreatitis.
Intestinal disorders.—Corrosive poisoning, enteritis, colitis.
Diseases of the thyroid gland.—Exophthalmic goitre, myxœdema.
Diseases of the pituitary body.—Acromegaly, gigantism.
Pregnancy, tumours of the uterus and ovaries.
Renal affections.—Functional and organic.
Chyluria.

It will be seen that the list includes a medley of conditions, many of which stand in no obvious relationship to each other. Some fall into what appear to be natural groups, such as the toxic varieties and those associated with lesions of the nervous system, but even these groups are to a great extent artificial, for in them are included varieties of glycosuria which differ widely in their nature, and for some of which several wholly distinct explanations may be suggested, all almost equally plausible.

There can be no doubt that different toxic substances induce glycosuria in quite different ways. Thus, the excretion of sugar which follows the administration of thyroid extract is evidently intimately related to that which results from over-activity of the thyroid gland, of which I propose to speak at some length in a later lecture.

Phloridzin glycosuria may serve as a type example of that which results from a failure on the part of the kidneys to retain the normal quotum of sugar in the blood, and Pollak [12] believes that the excretion of sugar which follows the administration of salts of uranium has a similar origin.

Other poisons, again, such as coal gas and carbon monoxide, probably owe their power of inducing glycosuria to the partial asphyxiation to which they give rise. Edie, B. Moore, and Roaf,[13] who have recently published the results of an experimental investigation of asphyxial glycosuria, arrived at the conclusion that the important factor in its causation is not a deficiency of oxygen, but the accumulation of carbon dioxide in the tissues. They point out that many of

[12] Archiv für Experimentelle Pathologie und Pharmakologie, 1911, Band lxiv., p. 414.
[13] Biochemical Journal, 1911, vol. v., p. 351.

the drugs which are excitants of glycosuria exert actions which lead in various ways to accumulation of carbon dioxide in the circulation, such as curare, morphine, and perhaps amyl nitrite. The glycosuria which accompanies general anæsthesia they regard as due in part to a similar cause, and in part to the direct physico-chemical action of the anæsthetic.

It would take me too long to follow the observers quoted into a discussion of the manner in which the accumulation of carbon dioxide brings about the excretion of sugar, but it should be mentioned here that some varieties of glycosuria which do not fall into the toxic group may not improbably have a like origin.

Georg Hoppe-Seyler [14] has described the vagabond glycosuria. He observed that tramps who had walked long distances on a diet of bread and potatoes frequently passed urine containing 0·5–0·7 per cent. of glucose on admission to an institution, but that the sugar quickly disappeared, even on a diet rich in carbohydrates, and did not return even after the administration of glucose on an empty stomach in doses calculated to tax the tolerance of a healthy man.

The glycosuria which follows immersion in cold water was observed by Glaessner [15] in cases of attempted suicide by drowning. It also was of a transitory kind.

The glycosurias which accompany diseases and lesions of the nervous system also constitute a miscellaneous group. The profound influence of the nervous system in controlling carbohydrate metabolism admits of no question; but nervous lesions may induce glycosuria in several different ways, as on the one hand by causing evacuation of the glycogen reservoirs, on the other hand by bringing about disturbances of the functions of the glands of internal secretion, and possibly in yet other unsuspected ways.

The latter portion of the list foreshadows a more systematic clinical grouping, according to the organ concerned in the causation of glycosuria in different cases, and the evidence bearing upon this question will form the chief subject of discussion in my second and third lectures.

In the present state of our knowledge no complete system of classification of the varieties of glycosuria on such lines is possible, and we must be content to wait until increasing knowledge places such a grouping within our grasp.

A Pathological Classification.

On the other hand, what may be called a pathological classification of glycosuria is already within our reach, and one based upon fundamental differences.[16]

In the one class we may group all those cases in which the excretion of sugar in the urine is the outward manifestation of the presence of excess of sugar in the blood, of hyperglycæmia; and in a second class, those in which the sugar content of the blood is normal, or even below normal, and in which the glycosuria must be attributed to a failure on the part of the kidneys to retain the normal quotum. There is no English word which expresses this renal shortcoming so well as does the German word "Durchlassigkeit."

However, such a classification is not very useful for practical purposes, seeing that the cases of the first, or hyperglycæmic, group are in such enormous excess that the practical outcome is much the same as if we were to classify human beings into pigmented individuals and albinos respectively.

The large hyperglycæmic group needs to be further subdivided by a deep line of cleavage into those cases in which the excess of sugar in the blood is the outcome of a metabolic derangement (a deficient utilisation and excessive mobilisation of glucose in the organism), and those in which the blood is temporarily overloaded with glucose by the emptying of the glycogen reservoirs, as in the "puncture glycosuria" of Claude Bernard. But here, again, the dichotomy rather chips off a fragment than effects a just division, for what may be called metabolic glycosuria embraces the great majority of all cases met with in clinical practice, and to this group belong all cases which can lay any just claim to the name of diabetes.

I am far from wishing to suggest that puncture glycosuria has no clinical importance. On the contrary, a transitory excretion of sugar which ceases spontaneously in a day or two, as we should expect a glycosuria due to emptying of the glycogen reservoirs to do, is not a very uncommon clinical event, and may follow insults to the organism of various kinds, such as severe injuries, mental and emotional shocks, surgical operations, or paroxysmal pains. This makes the study of the causation of glycosuria even more difficult than it would otherwise be, and increases the chance of our being led to incorrect conclusions.

To select a single example: in cases of cholelithiasis extension of inflammation to the pancreas is by no means a rare event, and when this happens glycosuria or diabetes results; but, on the other hand, the transient excretion of sugar which sometimes accompanies gall-stone colic is probably due to emptying of the glycogen reservoirs.

The glycosuria which results from impaired retentive power of the kidney is in no sense due to error of carbohydrate metabolism, although when the blood is continuously drained of sugar by renal defect, as in animals subjected to repeated injections of phloridzin, the attempt to keep up the normal supply to the tissues leads to a secondary metabolic disturbance, to wasting and breaking down of proteins in the organism, and to a condition which resembles diabetes in some respects.

A Clinical Classification.

From yet another standpoint, and this time a clinical one, cases of metabolic glycosuria may be grouped into three main classes, according to the manner in which the disturbed body chemistry manifests itself—namely, into those cases in which actual excretion of sugar does not occur in ordinary circumstances, but may be induced by a dose of glucose or of cane sugar which, although it may be large, would not be sufficient to produce glycosuria in a normal individual; those cases in which spontaneous glycosuria occurs for a time, or recurs intermittently, apart from any excessive taking of sugar; and lastly, those in which the glycosuria is continuous, or is only suspended for a time by the imposition of a more or less rigid dietary poor in, or as far as possible devoid of, carbohydrate constituents.

The dividing lines between these several groups are shadowy, and an individual case may pass through all three stages in the course of its development. Again, some of the exciting causes of glycosuria with which we are most familiar produce in some cases no obvious disturbance of carbohydrate metabolism at all; in others a mere lowering of tolerance for glucose, a potential glycosuria; in others a temporary spontaneous glycosuria; and in others again a continuous excretion of sugar which conforms to any definition of diabetes yet advanced.

Need of Prolonged Clinical Investigation.

I have already emphasised the importance of the accurate diagnosis of glycosuria, but it is a matter of no less importance that each individual case should be subjected to careful investigation over a considerable period of time. Only in this way can we hope to make any real advance in the study of the clinical aspects of our subject.

We cannot tell which cases are likely to deviate from the ordinary course, and many examples of temporary glycosuria, in themselves of great interest, have been rendered valueless by the lack of such investigation during the glycosuric period. Only when it has been already too late to fill in the gaps in the study of it has the phenomenon been recognised as transitory. Yet as such cases constitute the exceptions, and the immensely greater number follow the usual continuous course—which course can be foretold with some approach to accuracy after a few examinations, much labour will have to be wasted if we are to insure that all cases in which the excretion of sugar may prove eventually not to be persistent, shall be subjected to adequate investigation. Not really wasted, however, for our knowledge of diabetes is not yet so complete that the careful watching of ordinary cases can be dispensed with, either from the point of view of the advance of medical science or from that of the interests of the individual patients.

Nor is prolonged watching of any less importance than careful investigation during a special period, for experience teaches that recovery from glycosuria cannot be assumed to be permanent, until the case has been under observation for a long period after the urine has ceased to contain sugar. In many of the recorded cases the period of watching has been far too short to carry conviction.

Again, many descriptions are deprived of the value which

[14] Münchener Medizinische Wochenschrift, 1900, Band xlvii., p. 531.

they would otherwise possess by the absence of any evidence to show whether, after glucose has ceased to be excreted spontaneously, the patients have recovered the normal tolerance for carbohydrates, or whether the power of dealing with foodstuffs of this class has remained persistently lowered. It is not difficult to obtain information on this point by means of simple and easily applied tests, and concerning most of the cases recorded in recent years such information is forthcoming.

Such investigations of glycosuria and of diabetes from the standpoint of clinical medicine are still greatly needed; for this branch of the subject has until recently been somewhat neglected in favour of the study of the metabolism of carbohydrates and its derangements in disease. This latter has long engaged the attention of a succession of able and highly skilled observers, and to the control of the metabolic error our treatment has hitherto been mainly directed. Far be it from me to depreciate in any way the value of these fascinating researches which have done so much to advance our knowledge, and have conduced so much to the advantage of generations of diabetic patients. Rather would I plead for a similar extension of our knowledge of diabetes in other directions, and a concerted effort to get into touch with the diseases behind the syndrome—an effort in which chemical pathologists and clinical observers may well combine.

What is specially needed at the present time is further advance into the regions which were opened up by Minkowski's discovery of the effects of removal of the pancreas in dogs, and from many sides pioneers are beginning to press forward into the unexplored tract. One such newly developed field is the study of the effect of the administration of glucose and other sugars to healthy persons and to sufferers from various diseases, and of the conditions which influence the power of utilising the several individual sugars.

POTENTIAL OR ALIMENTARY GLYCOSURIA.

Many constituents of urine which, when present in considerable amounts, indicate deviations from the standard of health, can be shown by methods of special delicacy to be present in traces in normal urine. This is the case with albumin, and with glucose also.

The controversy warmly carried on around this question some years ago may now be regarded as laid to rest, and it is now accepted as a fact that the urine of normal individuals contains glucose to the amount of some 1 or 2 decigrammes in the output of 24 hours. However, such minute traces do not suffice to yield the tests in ordinary use, and we only speak of glycosuria as present when the amount of glucose excreted is such as may be detected by the reduction tests employed in clinical work.

Limit of Tolerance of Glucose.

Even glycosuria of such degree can be induced in healthy persons by the administration of sufficiently large single doses of glucose. In other words, the power of a normal man to dispose of sugar given by the mouth is not unlimited. The limit varies somewhat in different individuals, but it may be stated that on an average 150–200 grammes of glucose are required to cause glycosuria. A smaller dose is needed when the sugar is taken on an empty stomach than when it is taken within a short period after a meal.

The limit of tolerance is different for different sugars. For cane sugar it is much the same as for glucose; for lævulose and lactose it is somewhat lower. As small a dose as 20 grammes of galactose may cause galactosuria, and even as little as a single gramme of arabinose suffices to induce an alimentary pentosuria.

Only a very small fraction of the dose given reappears in the urine, and although with larger doses the output is increased, the percentage remains small, and there is nothing to suggest that all sugar taken beyond a certain amount is excreted unchanged. Van Noorden[17] found that the rate of increase with increasing doses varies widely in individual cases, and Raphael[18] observed the paradoxical fact that some persons appear to deal more efficiently with larger than with smaller doses.

It is a much debated question whether the limitation of the tolerance of normal human beings for glucose indicates that the power of dealing with sugar in the organism is limited and can be overtaxed by introducing an excessive dose of glucose into the alimentary canal, or whether some part of such a dose is introduced into the blood by what may be called a short circuit, and so avoids the metabolic changes to which it is ordinarily subjected in the liver. Naunyn[19] suggested that some part of the glucose taken passes on into the intestine and, entering the lymphatic channels, reaches the blood directly by way of the thoracic duct. The slight hyperglycæmia so induced might bring about the observed excretion in the urine.

In order to put this theory to a crucial test W. Schlesinger[20] ligatured the thoracic duct of dogs whose tolerance for glucose had previously been measured. He found that after a brief period of lowered tolerance, the possibility of inducing glycosuria by the administration of glucose practically ceased in the animals so treated, but that after a month or so the limit of tolerance was re-established, although not at its former level.

On the other hand, facts are coming to light which indicate strongly that the alternative explanation is the correct one, and that the normal limit of tolerance is the outcome of a balance of factors. That the limit may sink conspicuously when certain morbid conditions are present is an established fact, but it would also appear that, in the course of certain diseases, of which myxœdema is one, the limit tends to be conspicuously raised; so that the patient may exhibit no glycosuria after the administration of doses of glucose which would far overtax the tolerance of any normal subject.

The normal limit is far above any test to which it is likely to be put in ordinary life, and it must rarely, if ever, occur that spontaneous glycosuria results from excess of sugar in the diet of healthy individuals; and the supposition that the power of dealing with glucose is not unlimited is compatible with what is known of the working of other metabolic processes in the body.

Lowering of Tolerance of Starch.

This much, at least, is obvious—that a phenomenon which can be induced in any healthy man cannot be looked upon as morbid, whereas deviations from the normal limit, in one direction or the other, may be so regarded.

No dose of starch which can be taken induces glycosuria in a normal subject, probably because it is not converted into sugar quickly enough to overtax tolerance at any given moment. Hence, when a meal of starchy food, of whatever amount, causes sugar to appear in the urine, we are confronted with a definitely morbid phenomenon, and there is much to support the view enunciated by Naunyn, and held by most observers, that the so-called alimentary glycosuria ex amylo, as distinguished from alimentary glycosuria e saccharo, is nothing less than diabetes writ small.

This is so important a matter, and one about which so much apprehension exists, that I shall be pardoned if I dwell upon it for a moment.

The name alimentary glycosuria is often used in connexion with this phenomenon as a sort of diagnostic placebo, to avoid the use of the ugly term diabetes, and I am not disposed to quarrel with such employment of it (although it greatly impairs its scientific value) so long as it is clearly recognised that between the patient who only excretes small quantities of sugar after meals rich in starchy foods and the sufferer from the gravest form of diabetes the difference is merely one of degree, and that the interval between them is bridged over by intermediate cases of all grades. In a sense all diabetes is alimentary, although in the worst cases the response to restriction of diet is very slight.

The fact that a patient is subject to alimentary glycosuria ex amylo often escapes notice. He will probably complain of no symptom suggestive of diabetes, and I have known instances in which examination of a specimen of urine passed at mid-day has revealed its presence, although in repeated examinations of morning and evening specimens no sugar had been found.

I recently had under observation a man, aged 52, who stated that on one occasion ten years previously sugar had been found in his urine. During the following eight years frequent examinations had revealed no sugar, and none had been found by the medical man who sent him to me on account of a wholly different complaint. Some urine passed

[17] Die Zuckerkrankheit, fifth edition, 1910, p. 22.
[18] Zeitschrift für Klinische Medizin, 1899, Band xxxvii., p. 20.
[19] Der Diabetes Mellitus, second edition, 1906, p. 33.
[20] Wiener Klinische Wochenschrift, 1902, Band xv., p. 768.

at my house at 11 A.M. contained a small quantity of reducing substance, which was proved to be dextrose. He then went for a holiday, during which his urine was examined by two medical men, who found no sugar. Three months afterwards sugar was present in every mid-day specimen, but not in urine passed on rising or in the evening.

If this patient has had alimentary glycosuria ex amylo for ten years past it is remarkable that the condition has not become aggravated during that long period; and if, on the other hand, there has been a long interval of immunity, the case is none the less exceptional in its course.

When any doubt exists in connexion with a case of the kind under discussion it may be removed by the administration of a meal rich in starch. To such a meal the subject of alimentary glycosuria ex amylo will promptly respond by excreting sugar.

It is very important that the condition should be detected when present, and that the patient should be treated by a suitable restriction of diet at this so early and amenable stage of his complaint. If left unchecked, the diabetes from which he suffers will sooner or later become aggravated, whereas by appropriate treatment further developments may be postponed.

Such lowering of tolerance of starch is most often met with in men who have reached, or who have passed, middle life, as the initial symptom of the milder kind of diabetes which is common at that period of life. In younger subjects, in whom the diabetic symptoms so often develop in a remarkably sudden manner, such an initial stage, if present, usually escapes notice, and the malady is seldom diagnosed before the glycosuria is already persistent and pronounced.

Lowered Glucose Tolerance.

To return to alimentary glycosuria e saccharo. As we have seen, this symptom is exhibited in some measure by normal individuals, but just as we do not give the name of glycosuria to the excretion of sugar by normal persons, so also the term alimentary glycosuria is only applied to cases in which the tolerance of glucose is depressed below the normal limit.

It is customary when testing tolerance to administer a single dose of 100 grammes of glucose upon an empty stomach, but in many cases far smaller doses—such as 50, 30, or 20 grammes—suffice to induce glycosuria. As a rule, the excretion of sugar ceases after some three or four hours, but it sometimes happens that it persists for several days, a phenomenon which suggests the presence of an important derangement of carbohydrate metabolism.

Lowered glucose tolerance—to employ the least cumbrous name for a condition for which a simple designation is much to be desired—is associated with a variety of morbid states, but, like spontaneous glycosuria, it is capricious in its appearance, even in maladies which are amongst its recognised causes. Of two cases, apparently much alike, this symptom may be present in one and absent in the other.

Febrile disorders are amongst its common causes, and of others may be mentioned pregnancy, acute and chronic alcoholism; certain diseases of the nervous system, some functional and others organic; affections of the pancreas; exophthalmic goitre and acromegaly.

Lowered glucose tolerance is by no means a special feature of hepatic diseases; but, on the other hand, the more recent observations tend to confirm the opinion arrived at by H. Strauss [21] that a conspicuous lowering of tolerance of lævulose, as distinguished from glucose, is an important symptom in such diseases, and one of real diagnostic value in aiding the recognition of lesion of the parenchyma of the liver.

Significance of Lowered Glucose Tolerance.

Divergent views are held on the question whether lowering of glucose tolerance is to be regarded as the initial and slightest manifestation of that error of carbohydrate metabolism which culminates in diabetes, or has a wholly different significance from alimentary glycosuria ex amylo and spontaneous glycosuria. In discussing this question it must be borne in mind that where tolerance of starch is limited that of sugar is also lowered, so that these cases must be excluded from the discussion in which the two phenomena coexist.

If it be the true explanation of the fact that no dose of starch which can be taken excites glycosuria in a normal subject that the time required for the conversion of starch into sugar prevents the overtaxing of the metabolic processes at any particular moment, we may regard the difference as one of dosage, and if it can be shown that in some cases, although glucose tolerance is reduced to a very low level, glycosuria cannot be induced by starch, a strong *primâ facie* case will be made out for the essential distinctness of the two phenomena in some cases. Observations in which tolerance of starch has been tested side by side with that of glucose are not numerous, and more of such are greatly to be desired.

It is a significant fact that J. Strauss,[22] who carried out an extensive series of such observations upon patients suffering from specific fevers, and from alcoholism, by the administration of glucose, and of equivalent doses of starch, found that no small proportion of the patients tested exhibited alimentary glycosuria ex amylo, side by side with lowered glucose tolerance. Van Noorden looks upon J. Strauss's results as affording evidence that in the conditions investigated the potential glycosuria is due to implication of the pancreas.

Raphael,[23] also, who conducted an elaborate research upon glycosuria e saccharo, summed up in favour of the view that between lowered tolerance of glucose and of starch respectively the difference is rather one of degree than of kind.

Some cases of lowered glucose tolerance have developed under observation into cases of diabetes, but it would be of interest to know whether the tolerance of starch was fully tested in the early stages of these cases. That alimentary glycosuria e saccharo may be an early symptom of diabetes is undoubted, the question at issue is whether it should always be so regarded. For a final answer to this question our knowledge does not yet suffice, but this much may be confidently stated, that the fact that a patient shows lowered glucose tolerance in the course of some acute disease with which that symptom is wont to be associated, does not in any way imply that he is likely to develop diabetes later on.

The investigations of Barringer and Roper,[24] who followed up the after-history of a number of patients who had at some time exhibited spontaneous glycosuria, do not really help us to answer the question. They found that those patients who, during the sugar-free period, or after some years of immunity from glycosuria, were found when the test was applied to have definitely lowered glucose tolerance, were much more liable to become diabetic, than those whose tolerance of glucose was found to have returned to the normal level. Thus they demonstrated conclusively the value of tolerance tests in the estimation of the significance of a transitory glycosuria, and that persistent lowering of tolerance is to be regarded as a danger-signal; but their results also tend to prove that a patient may have his tolerance so far lowered that he exhibits spontaneous glycosuria for a time, and yet may be in comparatively little danger of developing diabetes, provided that his tolerance returns later to the normal level.

W. Schlesinger,[25] who is an upholder of the essential distinctness of glycosuria e saccharo, as a phenomenon not necessarily connected with the diabetic metabolic error, regards the excretion of unusually large quantities of sugar after the glucose test as affording evidence of a true diabetic tendency, a view which few will hesitate to accept. He also points out that whereas, when a particular sugar is given in excess some of that sugar appears unchanged in the urine, in some cases in which tolerance is lowered lævulose when so taken induces an excretion of glucose, and this event also he looks upon as an indication of a true metabolic derangement.

If when discussing this subject we take as our criterion of diabetes that the carbohydrate error be persistent as long as the patient lives, we beg the whole question, for, as I hope to show in my next lecture, some cases which exhibit for a time all the features which we regard as characteristic of diabetes, and even some in which the spontaneous excretion of sugar cannot be arrested by a strict dietary, do, nevertheless, end in what appears to be complete and lasting recovery. Unfortunately, these cases are so rare that we are not justified in holding out to our diabetic patients any expectation of so favourable an outcome of their ills.

THE PRINCIPLES OF TREATMENT IN EXOPHTHALMIC GOITRE.[1]

BY GEORGE R. MURRAY, M.A., M.D. CANTAB., D.C.L. DURH., F.R.C.P. LOND.,

PROFESSOR OF SYSTEMATIC MEDICINE IN THE VICTORIA UNIVERSITY PHYSICIAN TO THE MANCHESTER ROYAL INFIRMARY.

I HAVE been asked on this occasion briefly to consider the general principles of the treatment of exophthalmic goitre, as it is important that these should be clearly stated as a basis for the discussion on the best means of carrying them into practice by either medical or surgical methods.

Etiology.

It is now generally agreed that the symptoms of Graves's disease are due to a thyroidal auto-intoxication. In Graves's disease the secretory epithelium of the thyroid gland is superabundant, changed in type, and over-active. Whether the secretion which results from this state of affairs is of the same strength and composition as that which is produced in health does not materially affect the problem we are asked to consider on this occasion, as the general symptoms of the disorder are brought about by the circulation in the blood of a large excess of this product, whatever its actual composition may be.

We do not, as yet, know the actual exciting cause of the special proliferative changes which are found in the thyroid gland in exophthalmic goitre. We are aware that the disease may arise under certain predisposing conditions, but these vary in different cases and in many may be wanting altogether. When we are in possession of this information so that we can induce the disease at will in lower animals, the problem of the prevention and treatment of this malady will be greatly simplified.

In the present state of our knowledge the objects we have in view in the treatment of Graves's disease are either to remove the source of the auto-intoxication or to counteract its ill-effects. The principles of treatment are therefore comparable to those which guide us in the treatment of a disease which is due to a local microbic infection, giving rise to a general toxæmia, but more difficult to carry into practice.

In some cases we know that, either as the result of treatment or in the natural course of the disease, the hyperactivity of the thyroid gland gradually diminishes, the symptoms subside, and the patient recovers more or less completely. According to my own experience this may take any period from nine months up to seven or more years, from the commencement of the disease. In some chronic cases a certain amount of tolerance gradually becomes established so that the patient is hardly aware that the disease is still present. Recovery in these cases is the result of an involution of the enlarged gland, due to an atrophy of the redundant epithelium. This atrophy may be either primary in origin or secondary to the development of a gradual fibrosis of the gland, which may even proceed to partial or possible total destruction of the glandular epithelium, as in a case I have recently seen in which the symptoms of Graves's disease were replaced within a few months by those of myxœdema. We are greatly in need of more exact information as to the conditions under which those involutionary changes take place. If we possessed this knowledge we should be in a better position to bring this natural process of cure into operation.

Methods of Treatment.

We shall now briefly review the methods which may be adopted to reduce the morbid activity of the thyroid gland to a normal level or to counteract its ill-effects, reserving the consideration of surgical measures to the last.

General treatment by means of mental and bodily rest combined with a liberal diet, of which milk forms a large proportion, tends to diminish thyroidal activity. Excess of proteid food should be avoided, as Dr. Chalmers Watson's experiments show that the structure of the thyroid gland may be modified by diet. The work of Ehrlich and Wassermann opens up the possibility of efficient remedies being obtained in the future which may have a direct and selective action on the hypertrophied gland. It is not unlikely that arsenic and belladonna, which are of proved utility, act in this way and tend to depress the activity of the secretory cells, just as iodine, on the other hand, exalts it and aggravates the symptoms. With the same object in view attempts have been made to prepare a specific cytolytic serum which would induce destructive changes in the epithelium of the gland without injury to cells in other parts of the body. Unfortunately such preparations are not really specific in action, and if used in adequate amounts they produce degenerative changes in other organs as well, and consequently may do more harm than good. X rays have been employed in order to diminish the gland.

In one of my cases who was under treatment at the Manchester Royal Infirmary 11 doses of X rays were given between Nov. 28th, 1911, and Jan. 5th, 1912, by Mr. A. E. Barclay. On Jan. 9th the right lobe of the gland was removed because one night the patient had a severe attack of dyspnœa with loss of consciousness for 10 minutes. Microscopical examination of sections prepared by Dr. W. Mair from the portion removed shows there is a diffuse interalveolar fibrosis, which, in places at any rate, appears to be of recent origin and to be the result of the action of the X rays. At the time of the operation Mr. A. H. Burgess found the capsule of the gland was unusually adherent to the trachea and surrounding parts. These adhesions were probably also a result of the use of the X rays.

Although in this case no beneficial result was obtained by X ray treatment, the microscopical changes suggest that a more prolonged course of treatment might in time bring about the desired result. The application of a mild, faradic current to the goitre for two or three hours each day possibly acts directly on the activity of the gland, as in many cases it is a useful mode of treatment.

We may endeavour to counteract the ill-effects produced by the excess of secretion in the blood-stream. For this purpose the milk, dried blood, and blood serum of thyroidless animals, especially of sheep and goats, may be employed on the supposition that the products contain some substance which acts as an antidote and neutralises the action of the excess of thyroid secretion in the blood. In many cases we have to resort to purely symptomatic treatment under special circumstances so as to deal with the special crises which arise from time to time in Graves's disease, when special measures may be applied to relieve cardiac, intestinal, bronchial, cutaneous, or nervous crises giving rise respectively to severe palpitation, diarrhœa, bronchorrhœa, sweating, and the like.

Surgical Treatment.

Finally, I will briefly mention some points in connexion with surgical treatment. As the first object we have in view is to reduce the hyper-activity of the thyroid gland, it naturally occurred to many that this could be most successfully achieved by surgical methods. This view appealed rather strongly to me when the pathology of Graves's disease first became understood, but very quickly the hazardous nature of the proceeding became apparent. The first three of my cases in which one lobe of the thyroid gland was excised—in each case by a different surgeon—all died almost immediately after the operation. After this experience I was very reluctant for long to advise any patient to undergo operation, and consequently my personal experience of surgical treatment is limited.

Two methods of surgical treatment are chiefly employed at the present time: ligature of one or more of the thyroid arteries and partial thyroidectomy. On referring to the notes of 300 of the cases which I have seen, 276 of which were women and 24 men, I find that as far as I know only 10 have been operated on. In one case both superior thyroid arteries were ligatured, and in nine partial thyroidectomy was performed. In the first three cases, which were all in women, death occurred shortly after the operation. The other seven recovered from the operation, so that of the cases I have seen in which an operation was performed the mortality has been 30 per cent. Two of these seven were men and five were women.

In one man who had suffered for nine years from severe Graves's disease, both superior thyroid arteries were ligatured by Mr. R. Morison in June, 1907, under general anæsthesia, 4½ years ago. Marked improvement has taken place, so that he can now cycle to and from his place of

[1] A paper read at a combined meeting of the Medical and Surgical Sections and Section of Anæsthetics of the Royal Society of Medicine on Feb. 13th, 1912.

business and do an ordinary day's work, but he is not cured. In the second man, whom I saw in 1909 just before he started for Canada, partial thyroidectomy was performed by Mr. Roberts, of Toronto, in May, 1911, and when I saw him the following September he was quite well and completely cured of the Graves's disease.

Of the five cases in women, in one—that of a single woman, aged 32, in whom there had been a goitre for 12 years with more recent development of secondary Graves's disease—the right lobe was excised by Mr. W. G. Richardson in June, 1907, because she complained of so much pain in it and was anxious to have it removed. The only anæsthetic used was chloroform given through the Harcourt inhaler. At the time the heart was considerably dilated and the pulse 144. She recovered, and her medical adviser, Dr. A. Smith, informs me that she is now quite well.

In another case, that of a girl aged 15 when I saw her, the operation was performed by Sir Victor Horsley, and when last I heard of the patient marked improvement had taken place.

In the case of a woman, aged 32, under my care at the Manchester Royal Infirmary, Mr. W. Thorburn on August 16th, 1910, removed the right lobe of the gland under local anæsthesia. Before the operation the pulse-rate was 130; it is now 76, and she has improved considerably in other respects, but there are still well-marked exophthalmos, some general nervousness, and tremor of the hands. The left lobe is still moderately enlarged, so that she is not cured.

In a recent case in the Manchester Royal Infirmary, already referred to, Mr. Burgess removed the right lobe on Jan. 9th from a girl, aged 18, with severe Graves's disease, because after 11 doses of X rays she had an alarming attack of nocturnal dyspnœa with loss of consciousness lasting for 10 minutes. Ether was given by the open method. Before the operation the pulse varied from 204 to 120. She has recovered from the operation and is now steadily improving, the pulse varying from 120 to 92. In another case Mr. Burgess has also this month removed the left lobe, isthmus, and lower part of right lobe on account of stridor.

Thus in six of the ten cases an operation has been done in order to relieve or cure the Graves's disease, and three of them died. In the remaining four the operation was primarily carried out for the relief of pain or dyspnœa. Of the seven survivors two are cured, four are improved, and one has just recovered from the operation.

In conclusion, I would advocate operation in all cases where there is distinct stridor from compression of the trachea or persistent pain in the goitre. In cases of a mild type I do not consider an operation is necessary. In very severe cases with marked cardiac failure the risk is too great. In a certain number of cases of moderate severity in which no adequate improvement has resulted from medical treatment fully tried for 12 months, a partial thyroidectomy or ligature of the superior thyroid arteries may be advised. The remarkably small mortality from the operation obtained by Sir Victor Horsley, Dr. T. P. Dunhill, Professor Kocher, and others clearly indicates that the grave dangers which formerly made physicians unwilling to advise operation have now been considerably reduced, so that operation can be recommended in a larger number of cases than previously appeared to be advisable.

The chief points upon which we hope to obtain further information by this discussion are the exact indications for operation, the average risk, and the results. In considering the latter and in comparing them with those obtained by other methods of treatment I would emphasise the fact that the prognosis usually given in text-books is too pessimistic, as a very considerable number of cases do either completely or partially recover without operation.

Manchester.

LONGEVITY.—The death occurred at Bexhill on Feb. 12th of Mr. John Rogers, who had attained the great age of 102. He joined H.M.S. *Romney* in 1832, was in the navy 39 years, and had received a pension for 41 years. While living at Camber, near Rye, he was coxswain of the lifeboat there. He had never been laid up in his life until seized with his final illness.

CYSTITIS: ITS CAUSES AND ITS TREATMENT.

BY DAVID NEWMAN, M.D. GLASG., F.R.F.P.S. GLASG.,
SURGEON TO GLASGOW ROYAL INFIRMARY.

IN reviewing the important subject of inflammation of the bladder it will be shown that cystitis may be due to various pathogenic microbes differing greatly in their immediate action and ultimate results. The various modes of infection and the lesions produced by the different organisms will be examined, and the cystoscopic appearances and the changes produced upon the urine will be described. The complications commonly met with will be considered, and the treatment of all the varieties of the disease will be carefully and very fully discussed.

Causes of Cystitis.

Cystitis, either as a primary affection or secondary to other diseases of the kidneys or bladder, is one of the most common ailments of the urinary tract. Sometimes the onset is so mild and transitory as only to induce a slight increase in the demand to micturate, and in children or adolescents nocturnal incontinence. At other times the attack is ushered in by the most violent disturbance: great frequency in micturition with burning pain at the end of the act, and straining to expel even when the viscus is empty, so that at the termination of the effort blood squeezed from the congested mucous membrane alone escapes. These severe and local symptoms are accompanied by active disturbance of digestion, rigors, anorexia, and, of course, loss of sleep.

Whatever the degree of inflammation, it is immediately due to the propagation of pathogenic micro-organisms in the bladder, the most common varieties being bacillus coli, tubercle bacillus, streptococcus pyogenes, gonococcus, staphylococcus pyogenes aureus and albus, pneumococci, and urobacillus liquefaciens septicus, all of which are pyogenic and, with the exception of the three mentioned first, are urea-decomposing organisms.

Attempts have been made to divide cystitis into two classes—the infective and the non-infective; but while this classification may be convenient for teaching purposes, being contrary to fact, it is most misleading.

It is true that irritation of the bladder may be induced by the toxic action of drugs, such as cantharides, turpentine, and corrosive sublimate, by chemical irritants, and by crystalline deposits, but in the absence of active infective matter the irritation is transient, subsiding very soon after the exciting cause is removed; the urine remains acid and deposits only mucus, epithelium, and perhaps a small quantity of aseptic pus. But while it is universally recognised that microbes are the cause of cystitis, they are innocuous unless certain conditions are provided favourable to their propagation—namely, hyperæmia of the mucous membrane, retention of urine, or injury.

Many circumstances predispose a patient to cystitis by favouring the introduction of microbes or their proliferation after they have invaded the bladder. Under the former may be mentioned injuries to the bladder from sounding, the use of the cystoscope or urethral catheters, influenza, scarlet fever, enteric fever, diphtheria, septic and tuberculous lesions, infection of adjacent organs, and gonorrhœa; while under the latter may be included tumours of the bladder, chronic enlargement of the prostate, stricture of the urethra, foreign bodies in the bladder, paralysis of the bladder, and displacements of the uterus.

Microbes alone may fail to give rise to cystitis unless they have the power of decomposing urea. Tubercle bacilli, bacillus coli, and pneumococci may be found in the urine without any lesion in the urinary tract.[1]

The organisms which invade the bladder may be divided into two classes—those which induce decomposition of the organic constituents of the urine, and those which cause little or no chemical change in these substances. This distinction is a very important one. When organisms which do not possess the power of decomposing the organic constituents of the urine are introduced into the healthy urinary tract they fail to produce any serious effect. For example, a pure culture of the bacillus coli or of the tubercle bacillus may

[1] Renal Cases. By the Writer. James MacLehose and Sons. 1899 P. 146.

fail to induce cystitis when injected into the uninjured bladder, but if separately, or along with them, urea-decomposing organisms are introduced, acute cystitis is sure to follow. When the infection is "mixed" the progress of the disease is usually very rapid.

Excluding cases of catarrh of the bladder, where the irritation is the result of the action of chemical agents or of mechanical irritants such as vesical calculi, inflammation is the result of pyogenic micro-organisms. While aseptic chemical and mechanical irritants may conduce to the formation of small quantities of pus, the pus so formed is free from organisms, and when absorbed does not produce secondary abscesses. While this statement must be accepted, it is also obvious that the resistance of the part subjected to such continuous irritation may be seriously diminished. Consequently an injured bladder, or a bladder with a stone in it, is very liable to become septic.

Sources and Modes of Infection.

The organisms which produce morbid changes in the bladder do not differ from those found in other tissues; indeed, almost all the microbes which are pyogenic in man gain an entrance to the urinary tract, and have been discovered as causes of disease in these parts. The two most frequent sources of infection are from the intestine on the one hand and *viâ* the urethra on the other. In the former, from the blood, the organisms reach the bladder through the kidney or through the lymphatics; in the latter along the urethra.

There may be said to be three modes of infection:—

1. Ascending infection by the path of the urethra, which for obvious reasons is more common in women than in men—for example, in gonorrhœal and coli bacillus infection.

2. Descending infection or hæmatogenous infection, where the organisms are conveyed from a primary focus to the urinary tract by the blood and are excreted by the kidney. This happens in tuberculous, in typhoid, and in coli bacillus infections.

3. Transparietal infection through the lymphatics from the intestine to the bladder, as observed in appendicitis, in dysentery, and internal hæmorrhoids.

The first-mentioned channel of infection is most common in females, and in men the two latter paths are more generally followed.

The question of the mode of invasion, interesting as it may be from a pathological point of view, can only be referred to very briefly. What we desire more particularly to consider are the clinical aspects of the subject. Some notice, however, must be taken of the individual organisms in order to have a proper understanding of their mode of working, and the best methods of repelling their attack are of the first importance to the practical surgeon.

The Individual Pathogenic Organisms.

The *Bacillus coli communis* is by a long way the most common cause of cystitis—close upon 70 per cent. of the cases examined; and in the bladder, as elsewhere, its virulence varies according to circumstances. In some cases its presence causes little or no disturbance, while in other instances its virulence is great.

The bacillus coli, being absorbed into the circulation through lesions in the intestine, is deposited in the kidney or the bladder. This occurs most commonly when the intestinal tract is obviously diseased. It is found, as a matter of experience, that pyelitis, septic nephritis, or cystitis comes on very commonly in the course of convalescence from enteric fever, dysentery, or acute diarrhœa. Any injury of the intestine, or even injury of the tissues in its neighbourhood, seems to be suffcient to promote the emigration. After operations for appendicitis it is not uncommon to meet with transitory hæmaturia as a result of coli bacillus lesions in the kidney or bladder. Probably the microbes pass from the intestine very much in the same manner as serous fluid does, and from the same or similar causes; in fact, the two transudations are often coincident, but their relationship to one another is not fully understood.

The organisms taken as a pure culture from a peritonitis arising from a perforation of the intestine are found to be more virulent than when taken from a healthy intestine; or again, if the intestine be obstructed artificially the activity of the bacillus is also increased. Also, in different cases of pyelitis and cystitis degrees of virulence may be observed, and while the organisms derived from one case on cultivation and inoculation into animals may produce very mild effects, those taken from another case which appears to be exactly similar may induce very grave results. The bacillus coli seems also to have the power of increasing the activity of other bacilli or of rendering their product more harmful.

The bacillus coli produces a hæmolysin and an endotoxin, but the opsonic and phagocytic indices and the agglutination reactions are of little or no value. By staining reactions alone the bacillus cannot be distinguished from bacillus typhoid or bacillus proteus, and to identify it a culture test is required.

When a bladder containing a phosphatic stone becomes infected with bacillus coli the surface of the stone becomes honey-combed and covered with a layer of soft mucus which completely envelops it and protects the mucous membrane, and at the same time the calculus is gradually eaten into and becomes very friable, and on account of the mucous covering is difficult to discover with a sound.

Tubercle bacillus is found in the urine most frequently in tuberculous nephritis, and may cause a secondary infection of the bladder. It is seldom that the bladder is the first part of the urinary tract attacked, but primary vesical tuberculosis is occasionally met with. It is not often encountered as a complication of phthisis pulmonalis, but in association with tuberculous disease of the bones and joints it is frequently seen, and in such cases, the infection being by way of the kidneys, the base of the bladder near the ureteral orifices is first attacked. Indeed, in cases of early tuberculosis of the kidney the appearances presented by the orifices of the ureters and the mucous membrane around them are often the first indication of the renal lesion.[2]

The bladder offers considerable resistance to the attack of tubercle bacillus even when the mucous membrane is injured, as shown by experiments. Rovsing has demonstrated that tubercle bacilli injected into the bladder and allowed to remain often fail to produce a lesion. This explains how it is that in many cases of tuberculous nephritis the bladder remains healthy. But if other pyogenic organisms are present the resisting power of the mucous membrane is greatly weakened, and secondary infection is almost certain to occur.

It is more difficult to obtain the bacilli from urine than from sputum; they are less numerous in proportion to the medium in which they lie; in urine the processes of decomposition destroy them more rapidly, and smegma bacilli are apt to be mistaken for them. Koch, König, Leyden, and others have endeavoured to distinguish these bacilli from one another by staining methods but have failed. Muir, however, says: "We have found that in smegma it can be readily decolourised by a minute's exposure to alcohol, after the usual treatment with sulphuric acid, and thus can be readily distinguished from the tubercle bacillus." The former is non-pathogenic when inoculated into animals.

According to Tilden Brown, the most favourable time to look for the tubercle bacillus is immediately after a hæmaturia. This may be so, but I have found that it is in the samples of urine containing heavy purulent particles that the bacilli are most abundant, and that they are most readily found when the deposit from freshly passed urine is examined by the aid of the centrifuge. The microscope cannot be relied upon to prove a negative. In some instances the bacilli in the urine are so few in number that it is difficult, or almost impossible, to discover them simply by the microscope; in such instances inoculation experiments may help to clear up the diagnosis.

Tuberculosis can be communicated artificially to animals in many different ways—in fact, through any of the channels of access to the body. When tuberculous urine is injected subcutaneously into guinea-pigs or into rabbits it produces a typical tuberculosis within 10 or 12 days.

Normal urine when aseptic becomes absorbed without producing any evil effect, or when septic it may produce a suppurative peritonitis. If, however, the experiment is performed with care, healthy urine produces a negative result, but if the urine contains tubercle bacilli or their spores acute miliary tuberculosis is developed in the course of a few weeks, when the injection is made into the peritoneum, or if the urine be placed underneath the skin a hard tuberculous nodule is formed.

The *streptococcus pyogenes* not infrequently gives rise to septic infection of the urinary tract and brings about diffuse

[2] The Surgical Aspects of Early Renal Tuberculosis. By the Writer. Practitioner, vol. lxxxvii., No. 1, p. 8.

inflammation and suppuration. When present in pure cultures it does not decompose urea, but it is frequently associated with the presence of other organisms possessing that power; consequently it is generally found in alkaline urine. In character it closely resembles the streptococcus of erysipelas, and by most observers the two are regarded as identical.

Pneumococcus infection of the kidney may cause very acute and grave symptoms and sometimes involve the life of the patient. It is a condition which has not been sufficiently recognised, being liable to be mistaken for acute nephritis, but the appearances of the orifices of the ureters are very striking and characteristic, and not uncommonly the disease is limited to one kidney.[3]

The writer has met with a number of cases within the last five years where the disease has been unilateral, and in a few marked improvement has been obtained by incision of the fibrous capsule to relieve tension of the swollen parenchyma. While the renal lesion is usually the most serious, the bladder also becomes infected and an acute cystitis develops. The invasion is never limited to the bladder only, and on cystoscopic examination the hyperæmia is most marked around the ureter orifice of the affected kidney.

We may now consider the micro-organisms which cause decomposition of urea, and are, therefore, found in alkaline urine only.

The *staphylococcus pyogenes aureus* is one of the most virulent septic organisms and is very widely distributed, occurring in almost all suppurations, in normal saliva, in water, in dust, in the air, and especially on the surface of the skin. When it gains access to the urinary passages it rapidly propagates, causes decomposition of urea, and the alkaline urine, by acting upon the mucous membrane, reduces its resisting power and facilitates the entrance of the organism into the tissue.

Staphylococcus pyogenes albus is less malignant than the yellow form, but closely resembles it, and by some bacteriologists is regarded as a variety of the organism described above; it seems, however, impossible to transform the one organism into the other.

Besides those above mentioned, there are many other varieties of organisms found in the urine in inflammatory diseases of the urinary tract, but these are the most important.

Gonococcus is often associated with cystitis, but whether it does by itself cause inflammation of the bladder is still a question unsettled. Doubtless it causes inflammation of the seminal vesicles, which is liable to be mistaken for prostatitis, and gives rise to troublesome symptoms, sexual neurasthenia, spermatorrhœa, occasional pain in micturition or on pressure on the perineum. These phenomena are magnified by the patient, and their treatment may require much care. If the infection become a mixed one the disease is very likely to extend to the bladder.

Mixed infections are generally more virulent than pure ones. For example, a simple gonococcus, bacillus coli, or tubercle infection may for a time remain quiescent or cause little trouble when pure, but if contaminated by any of the urea-decomposing organisms an immediate change is observed by marked increased activity of the disease.

Classification.

The classification of cystitis according to the nature of the infection may be a strictly accurate one from the pathological point of view, but from the practical side it is more convenient to group the cases in relation to the severity of the symptoms—in other words, not according to the individual organisms giving rise to the malady, but according to the amount of disturbance produced by their propagation. As has been already pointed out, the same organism may in one case produce very little discomfort, while in another case the symptoms may be very severe and prolonged.

Cystitis may be (I.) mild, (II.) severe, or (III.) chronic.

I.—*Mild Cases.*

Juvenile incontinence or involuntary nocturnal micturition in children and adolescents is frequently due to a mild infection of the bladder by colon bacilli, which may give rise to symptoms of a general character liable to lead the medical attendant astray as to the cause of the trouble. Following upon an attack of measles, colitis, or appendicitis, or consequent to chronic constipation or persistent diarrhœa, the bladder of a child becomes infected.

Another fruitful source of infection in female infants is napkins. A careless mother or a nurse, in place of supplying clean napkins, simply dries the soiled ones, using them several times without washing. These cause scalding of the perineum and adjacent parts, including the vagina and urethra, followed by symptoms of cystitis. When the attack subsides a certain amount of bladder irritation remains, and as the patient passes from infancy to childhood nocturnal incontinence manifests itself, and very commonly the sufferer is blamed for carelessness not her own by those who should not have allowed the infection to have taken place.

Nocturnal incontinence in young girls (not in boys, with them the trouble is due to other causes), which continues in spite of all care and treatment, becomes a source of anxiety and annoyance to the parents, as well as of discomfort and discredit to the child. During deep sleep urine is passed, and the child is conscious of its escape only when she awakes. The flow is not because of inability of the bladder to retain an ordinary quantity of urine, but rather to undue readiness to contract when the reflex action of the vesicular muscular coat is uninfluenced by the will.

When due to extrinsic causes such as caruncle, fissured anus, rectal polypi, hæmorrhoids, ascarides, thread worms, &c., the infirmity usually disappears when the cause is removed, and in other instances as age advances it becomes less and less troublesome. In a few cases, however, the incontinence continues till puberty or even after that period has arrived. Often these patients are highly impressionable, so-called "neurotic," and this is blamed for the continuance of the "bad custom." It is supposed that the "habit" has been accidentally set up, and its persistence "may result solely from repetition through the force of custom, long after the original cause has disappeared."

While this view may possibly be true in a few instances a more probable explanation is that the nervous symptoms and the incontinence are the result of a common cause—namely, bacillus coli infection of the bladder—the former symptoms being due to a mild toxæmia, the latter to an irritable condition of the neck of the bladder. Cystoscopy shows in many of these cases a congested neck and slight hyperæmia of the mucous membrane, the urine contains an undue quantity of clear mucus, a deposit of epithelium, and bacilli coli. On adopting local treatment, which will be referred to later on, the disagreeable symptoms disappear.

Cystitis of pregnancy is usually met with in young women about the fifth or sixth month, and is moderately acute as a rule but sometimes severe. Those who are familiar with the varying conditions and reactions of urine of different healthy individuals, and of the same person at different times, must have observed that some samples undergo decomposition with great rapidity, while others remain unchanged for a considerable time. This remark refers only to urine which is sterile when passed. The tendency to early decomposition of urine in such cases is due to the excretion containing waste products capable of easy decomposition. Consequently we find that when a woman is suffering from imperfect digestion, nervous disturbance, or constipation, the urine decomposes early. It is probable that during pregnancy the excretion is modified considerably and is rendered a more suitable medium for the proliferation of organisms.

Since the time of the ancients changes in the urine have been noticed, as well as other phenomena having their origin in the glandular system; but even now the particular liability of the bladder to bacillus coli infection during pregnancy has not been sufficiently emphasised. The onset of the attack is generally associated with a history of chronic constipation and engorgement of the colon. The onset is sudden—an acute rigor, discomfort over the bladder and hypogastrium, painful and frequent micturition, temperature elevated and irregular, pulse rapid, and tongue furred. Soon the patient complains of widespread pain in the back, loss of appetite, headache and depression, and all the symptoms of toxæmia. On examination complaint is made of pain on pressure over the kidneys and bladder. The kidneys are found to be enlarged, and there are tenderness and rigidity of the lumbar muscles, and leucocytosis, polymorphs, and red blood corpuscles show evidence of anæmia. The urine is acid, smoky, contains some albumin, pus, and squamous

[3] See Brit. Med. Jour., March 31st, 1906.

epithelium. The odour is not offensive at first, but on standing soon becomes so.

These cases generally recover in a short time from the acute symptoms, but they are referred to here because, unless care be taken to effect a complete cure, women so attacked during pregnancy are liable to suffer after delivery from continued irritation in the bladder, which is only too liable to be left unheeded. Often the symptoms are so severe that the family doctor suspects stone, but not finding one on sounding, satisfies himself, but not the patient, with palliative treatment, which is totally inadequate for the condition. An examination shows the symptoms to be caused by inflammation of the neck of the bladder or the urethra. This disease may also cause caruncle, but when it is removed the symptoms are not completely relieved.

Chronic inflammation of the neck of the bladder and ureteritis, beginning in an attack of cystitis during pregnancy or just after delivery, is the most common cause of bladder irritation in women. It is due to bacillus coli infection, and must be regarded as one of the most fertile sources of ascending pyelitis and pyonephrosis.

II.—*Severe Cases.*

In acute cystitis the symptoms are constitutional and local, and may be due to pneumococcus, streptococcus, bacillus coli, gonococcus, or tubercle bacillus. The onset is sudden, often with a rigor, the temperature is raised and may be distinctly febrile; the pulse is rapid, and the tongue is coated, the digestion disturbed, the stomach and intestine distended with gas, and the bowels constipated.

The patient is unable to sleep because of the pain and frequent calls to micturate. As soon as the desire comes it must be gratified—the urgency is sudden and imperative. During the act the discomfort is great, but it is at its termination and for a variable time thereafter that the burning pain is most severe. The patient not only strains to get rid of the last drops of urine, but there is tenesmus.

This is the most important symptom. The bladder contracts powerfully, but the sphincter contracts as well, so that for a time nothing happens; the viscus cannot be emptied. Then the spasm at the neck of the bladder yields for a moment or two, and a few drops of urine are permitted to escape. Repeated evacuations of this kind occur and are associated with severe pain in the rectum, the perineum, and the point of the penis. After the viscus has emptied itself its muscular wall continues to contract and squeezes from its congested mucous membrane a few drops of pure blood.

Between the acts of micturition the patient suffers from a dull, aching pain over the pubis, which is increased on pressure and by the gradual filling of the bladder, and as the organ becomes distended a sense of weight and tenderness develops in the perineal region.

The urine is either acid or alkaline, according to the nature of the infection, and not, as it sometimes is stated, according as there is free escape or obstruction to the flow of urine. If the organism be a urea-decomposing one the urine is alkaline, cloudy, contains a large quantity of mucus and pus, some blood which is not readily thrown down, and probably also crystalline deposits of phosphates and urates of ammonia; but if the inflammation be due to the presence of bacillus coli, tubercle bacillus, or pneumococcus the urine remains acid for some time after being passed, is cloudy, contains little mucus or pus, and what blood is present deposits readily, along probably with oxalate of lime or uric acid crystals.

Cases of acute cystitis do not call for a cystoscopic examination unless the presence of a foreign body is suspected. The cystoscopic appearances depend upon the stage of the disease and the character of the infection, but these will be described later on.

Cases of acute cystitis generally recover under suitable treatment in ten days or a fortnight, but occasionally while the constitutional disturbance subsides the local symptoms continue in a less pronounced form. Should this be so an inquiry must be made as to the cause. There may be some obstruction to the escape of urine from the bladder—stricture of the urethra or enlarged prostate in the male, displacement of the uterus in the female, and vesical tumour or stone in both sexes. Or, as is frequently found, the urine remains infected, and unless careful local treatment is adopted the disease becomes chronic.

III.—*Chronic Cases.*

Chronic catarrh of the bladder is often the result of some blockage to the escape of urine; but, on the other hand, not infrequently it is the cause of obstruction.

Gradually increasing hindrance to the escape of urine leads mechanically to certain changes in the bladder, quite independent of any inflammatory action. The pathology may be considered according as we have: (1) Obstruction without inflammation; (2) inflammation with obstruction; and (3) inflammation without obstruction.

1. *Obstruction without inflammation* of the bladder is probably best seen in chronic cases of urethral stricture or enlarged prostate. In studying the changes care must be exercised in selecting cases where there has been no history of bladder trouble, and where catheter specimens of the urine are sterile, otherwise the problem becomes confused. Certain changes may be induced by obstruction alone, others only when the blockage to the escape of urine is associated with infection of the bladder. Simple obstruction to the escape of sterile urine leads to three changes only—dilatation of the bladder, atrophy of the mucous membrane, and sometimes to moderate hypertrophy of the muscular wall. Stagnation alone cannot cause cystitis; it predisposes to it only.

2. When the *obstruction is complicated by infection* of the bladder even to a mild degree, as seen in some forms of bacillus coli invasion, the retardation to the escape of urine produces graver changes. Not only are there calls for increased power of expulsion, which is met by hypertrophy of the muscular coat, but, acting upon an inflamed and softened mucous membrane, increased tension of the urine within the bladder during micturition forces the mucous membrane outwards between the muscular trabeculæ, which form a prominent network. By this process the interior of the bladder may become very irregular and small adventitious sacs may project beyond its wall.

3. *Inflammation of the bladder* is marked by hyperæmia of the mucous membrane and rapid cell proliferation in the connective tissue. This produces thickening of the whole wall of the viscus, together with fatty degeneration of the muscular elements, so that the usual trabecular appearance may be obscured by the thickening of the mucous membrane. The cavity of the organ may undergo considerable contraction, and when exposed through a suprapubic wound as much as a third of an inch of bladder wall may require to be cut through before the cavity is opened. The perivesical veins are found to be greatly gorged and the fat around the organ increased in amount. If the organisms are urea-decomposing ones the surface may become encrusted with phosphates and eroded. Usually ulceration indicates either tuberculous or malignant disease, especially if the ulcers are large in size or irregular in form.

Cystoscopic Appearances.

Cystoscopic appearances vary according to the nature of the infection, the stage of the disease, and the complications accompanying the cystitis.

In *mild bacillus coli infection*, such as gives rise to nocturnal incontinence in girls and young women, or in that so often associated with pregnancy, comparatively little change can be seen in the appearances of the interior of the bladder. The most notable lesions are congestion and swelling around the neck of the bladder and in the area of the trigone; elsewhere the mucous membrane is often anæmic, and here and there may be noticed little islands of less congested mucous membrane.

When caused by *gonococcus* the mucous membrane is deeply congested, swollen, and thrown into irregular folds. This is most marked close to the neck; elsewhere the mucous membrane may be simply streaked, and here and there may be seen small submucous hæmorrhages.

In *acute cystitis from pneumococcus* the infection of the bladder is always secondary to that of the kidney, and as a rule the inflammatory changes are not very marked, being limited usually to the orifices of the ureters and the trigone. The vessels are very distinctly seen, being clearly mapped out; the congestion is patchy, but there is not much œdema or swelling of vesical mucous membrane. There is no ulceration or hæmorrhage.

Acute cystitis arising from streptococcus infection differs from those above described in that the inflammation is more widespread. The urea-decomposing organisms rapidly set up serious changes in the bladder, and if the condition be

not relieved within a short time it may lead to very serious consequences. The meatus is usually contracted, the mucous membrane swollen, congested, and pouting from the opening so that the cystoscope is introduced into the urethra with difficulty, even although under normal conditions the lumen of the canal may be good. The urine is blood-stained, and on attempting to introduce fluid into the bladder it is at once expelled. By using an anæsthetic a view may be obtained, when the whole surface of the mucous membrane will be seen to be of a dark-red or purple colour. It is swollen, often numerous submucous hæmorrhages are seen, and in some places ulceration may have taken place.

In *chronic cystitis due to bacillus coli* the symptoms are frequently troublesome and difficult to get rid of, but as a rule the changes seen in the bladder are not serious; indeed, these are often surprisingly slight, and may be limited to the base and neck. Patchy congestion without much thickening of the mucous membrane is the most common change from the normal, and unless the observer has considerable experience the lesion may escape notice. The bladder may be infected for years with a mild variety of bacillus coli, giving rise to much discomfort, without showing very obvious evidence of disease beyond what has been described above until enlargement of the middle lobe of the prostate leads to obstruction. This change in the prostate is very commonly preceded by a bacillus coli invasion of the bladder. In the majority of cases, however, the mucous membrane is congested and covered with thin flakes of muco-purulent material.

In *primary tuberculous cystitis* the vessels ramifying the mucous membrane are obscured and the cytoscopic field is often ill-defined, probably due to œdema of the mucous membrane. The surface may be unduly pale elsewhere than in the immediate neighbourhood of the tuberculous infiltration. The deposit may be in the form of short bands, or in irregular patches which are generally covered with thin pale flecks of mucus or necrosed mucous membrane. When these are removed by washing an irregular eroded surface is seen, surrounded by a zone of hyperæmia. These tuberculous lesions are most commonly observed on the posterior and superior aspects of the bladder. Little tuberculous pustules may be seen or small caseous masses.

Chronic tuberculous cystitis presents a very varied appearance to the cystoscope. In cases of primary tuberculous cystitis the mucous membrane may be moderately injected and the vessels in its walls more numerous than normal. Extending along the floor of the bladder there may be a pale mass not unlike œdematous granulation tissue, and in it a number of small, white, or grayish yellow nodules or caseous points, some of which may be breaking down and discharging flaky pus. Or the lesion may appear as small caseous masses covered by very thin mucous membrane. These nodules may be round, oval, or sausage-shaped, the most prominent part being almost white in colour, while the immediate surroundings are bright red and contrast markedly with the anæmic mucous membrane of the bladder. Or the tuberculous process may begin by the formation of tubercles in the mucous membrane, and these, breaking down, form in a typical manner the so-called lenticular ulcers characterised by a flat base covered by caseous matter and sharp ragged borders, within which little miliary nodules are situated.

In the earlier stages of secondary infection irregular patches of hyperæmic mucous membrane are seen in the trigone or neighbourhood of a ureter orifice, and are covered by grayish-white flakes partly loose, partly adherent to the eroded surface. In other areas there may be small ulcers, covered by sloughs, while the margins of the ulcer are deeply injected and of a bright red colour. The smaller ulcers may be rounded, with minute caseous areas in their centre.

In the more advanced cases of tuberculous disease the whole of the mucous membrane becomes thickened and more or less eroded, the ulceration is widespread, and the ulcers vary much in form and appearance. They are, however, generally rounded and encircled by rings of deeply injected mucous membrane, covered with blood-clot or by bright yellow sloughs. The necrosed patch may appear of a bright green colour and have an irregular yellow ring close to its margin. In extreme cases, where a mixed infection has taken place, almost the whole surface of the mucous membrane may be destroyed.

While at first circular, by coalescence the ulcers may acquire various irregular forms. Their favourite seat is—probably on account of the mode of infection—the trigone and fundus of the viscus. In 73 cases the situations occupied were: the trigone, 21; the orifices of the ureters, 23; the base, 12; the posterior wall, 10; the neck, 4; and the anterior wall, 3.

The Urine.

In the beginning of a cystitis, especially when due to infection by bacillus coli or tubercle bacillus, the urine is little changed from normal; but, if the inflammation be acute, red blood corpuscles, epithelium from the bladder, and the organisms causing the irritation will be found. Also, in practically all cases the quantity of mucus is increased—to a slight degree in infection by the organisms found in acid urine; very greatly increased if the urea-decomposing organisms be present.

Pyuria.

Pyuria is the most important physical sign of cystitis as well as of inflammatory lesions in other portions of the urinary tract, and for diagnostic purposes it may be well to study the appearance of pus in the urine in detail.

The aspect imparted by the addition of pus varies according to the amount present and the character of the other morbid constituents in the urine. In cases where the pyuria is due to septic lesions of the kidney only the pus appears as a thick, opaque, creamy sediment, which on standing is rapidly and almost completely precipitated from an acid urine; the supernatant fluid is comparatively clear, is free from mucus, and does not decompose rapidly. On the other hand, where the pus is derived from the bladder alone, or in conjunction with a renal lesion, pus is not deposited quickly; when it falls it is precipitated along with glairy mucus, the urine in which it remains partly suspended is alkaline, and decomposition often begins before the urine escapes from the bladder.

The time at which the pus appears in the stream should be ascertained if possible. The appearance of pus at the beginning of micturition, during the whole flow, or at the end of the act only, lends additional significance to the symptom. For differential diagnosis the three-glass test is the best. The patient should first pass into glass A an ounce of urine, into glass B the bulk of the contents of the bladder, and into glass C the last ounce or so. These three samples should be examined separately.

Suppose the patient has a posterior urethritis or chronic prostatitis, the muco-purulent matter lodged in the urethra is washed into the first glass, while the second sample is free from pus or blood. In cases of cystitis the amount of foreign matter is the same in all three samples, unless when there is ulceration at the neck of the bladder or a stone is present. In these circumstances the last few drachms of urine may contain more blood or pus than that passed earlier.

Pus from the urethra, as in hæmaturia from the same situation, escapes independently of micturition, or is only mixed with the first few drops of urine—in fact, together with the presence of pain in the region is usually sufficient to determine its origin. In such instances the quantity of pus is usually small, and appears in flakes or threads. These are casts of ducts leading into the urethra, or threads of pus and macerated epithelium from granular patches swept away in the first portion of the stream. These urethral casts or shreds must not be mistaken for somewhat similar discharge occasionally observed in tuberculosis of the urinary tract. When urethral in origin they can be expressed from the canal before and after micturition. When the inflammation is situated in the posterior part of the urethra it may give rise to vesical irritation and some obstruction to micturition. The diagnosis can generally be cleared up by pressure upon the urethra in the perineum or rectum towards the end of micturition, when pus is found to exude.

It is otherwise in *catarrh of the bladder*, in which case the pus only escapes mixed with the urine; it is more or less abundant, and is accompanied by a number of large vesical epithelial cells. Vesical catarrh is generally associated with considerable pain on micturition and inability to retain urine for any length of time. A small quantity of pus in an acid urine is not necessarily of much significance, as it may be due to the slight catarrh caused by bacillus coli seen so frequently in uterine and ovarian disease, but it may also be one of the earlier symptoms of tuberculosis. The urine is generally of a pale greenish-yellow colour and the pus is

deposited on the bottom and sides of the glass in waves, the thickness of which diminish from below upwards. When the irritation is more severe, and especially when due to the action of urea-decomposing micro-organisms, not only is the quantity of pus increased, but much mucus may be secreted. So long, however, as decomposition does not occur, the pus and mucus separate as distinct deposits on standing, but if the urine becomes alkaline before evacuation the pus becomes thick and glairy, and remains suspended along with the mucus. To establish the fact that there is cystitis is not sufficient; the cause of the altered condition must be determined, and this may be done by a cystoscopic examination.

Hæmaturia.

Hæmaturia may be present or absent in uncomplicated cases of cystitis, and, as a fact, is not of so great diagnostic value as pyuria. It is important to observe the time at which the blood appears in the stream, and in order to do this it is necessary for the surgeon to see the patient urinate, and to observe whether the colouration is equal during the whole continuance of micturition, or is more abundant at the beginning or at the end of the act. The appearance of blood at the beginning of micturition, the remainder of the flow being clear, may be an indication of two distinct conditions—the lesion is either in the prostate, close to the neck of the bladder, or a malady or injury is present in the urethra.

In some lesions of the prostate the blood may pass into the urethra and accumulate there; so also in lesions of the first portion of the urethra the blood may flow backwards into the bladder and mix with its contents. When the blood originates in the urethra and accumulates there, or when it escapes from the prostate and flows into the urethra, the hæmaturia is limited to the beginning of micturition, but if the quantity of blood be great and flows backward into the bladder and mixes with its contents, then the whole of the urine becomes more or less coloured. Again, in a lesion at the neck of the bladder giving rise to hæmorrhage the hæmaturia is not limited to the beginning of micturition, but blood is also observed to escape at the end of the act. This is easily explained: between the acts of urination the blood accumulates in the urethra or close to its internal orifice, and is expelled with the first few drops of urine only, that following being clear; but again, before complete contraction of the bladder occurs a fresh hæmorrhage is induced, which shows itself in the urine last ejected.

When the hæmorrhage is due to injury or disease of the urethra the nature of the lesion is generally clearly indicated by the circumstance that the blood is observed to escape quite independently of micturition; sometimes, indeed, blood is seen to flow from the meatus spontaneously. In cases of tumour of the bladder, and also in vesical calculus, the hæmorrhage is most profuse at the end of micturition.

In acute cystitis the hæmorrhage is not severe, although almost pure blood may escape at the end of the act of micturition; but in chronic inflammation with ulceration large quantities of blood may be lost, and is ultimately mixed with a highly purulent and decomposing urine. In many cases of hæmaturia the only abnormal constituent in the urine is blood, while in other cases it is mixed with pus, mucus, tuberculous material, portions of tumours, or micro-organisms. The mixture of the blood with deposits of another kind requires only to be mentioned here. The three most common are pus, mucus, and tuberculous débris.

If the urine is placed in a conical glass and allowed to stand for a few hours, and the glass is then held up to the light, if pus be present in any great amount the deposits will be found in distinct layers like geological strata; the bottom of the glass is occupied by a yellowish deposit which may be more or less blood-stained pus, or, in some cases of renal pyuria, the pus may carry down almost all the blood corpuscles so as to leave an almost quite clear supernatant fluid.

When mucus is present, on the other hand, not uncommonly the blood corpuscles may be thrown down first, forming a layer at the bottom of the vessel, and following on this may be seen a layer of glairy gelatinous material, which may have a reddish tint or may contain a multitude of minute bloody streaks which intersect it and penetrate into all parts of this gelatinous layer. In such cases the hæmorrhage is usually due to some lesion in the bladder, and the presence of such an amount of mucus is generally indicative of a more or less acute vesical catarrh from infection by urea-decomposing organisms.

The tuberculous deposit can only be distinguished by microscopic examination or by inoculation experiments. Beyond demonstrating the presence of blood-casts of the uriniferous tubules, the microscope may reveal the existence of other elements of consequence in the deposit. For example, the character of the epithelium as derived from the renal parenchyma, from the pelvis, the ureter, or the bladder may greatly assist one in diagnosis; or, on the other hand, should the urine contain small fragments of tumours, parasites, or bacteria the hæmorrhage may be explained.

Complications.

Complications of cystitis are various; some may be regarded as causes, others as effects of the inflammation.

For example, a *calculus* may be either the effect of cystitis, or the cause. Subacute or chronic cystitis has existed for a considerable time; there may be inflammatory enlargement of the prostate as the result; small hæmorrhages occur and a calculus forms around a blood-clot. In such a case the removal of the stone does not cure the cystitis—further treatment is required.

On the other hand, a stone enters the bladder from the kidney; after an interval symptoms of irritation develop—are increased by exercise and relieved by rest. Over-exertion sets up an acute cystitis, the urine is acid, the patient experiences immediate benefit from complete rest, and removal of the stone is at once followed by cure.

The same remarks apply to *enlargement of the prostate.* The cystitis may be primary, leading to an inflammatory increase in the size of the gland, or the obstruction and stagnation caused by hypertrophy of the prostate may predispose to septic infection of the bladder. When the former condition exists the rest obtained by a suprapubic drain generally effects a cure, whereas in the latter removal of the prostate is indicated.

Urethritis involving the upper third of the canal is a very common cause of painful and frequent urination in women, and can only be detected by examination with the urethroscope. When discovered and suitably treated an immediate cure is effected. This will be referred to under treatment.

Hypertrophy of the muscular wall of the bladder has already been mentioned as a result of chronic cystitis, but while the two conditions are frequently associated, as a rule there is added to the inflammatory changes obstruction to the escape of urine. Two forms of hypertrophy, the eccentric and the concentric, are described. In the former the capacity of the bladder is increased, in the latter it is diminished, but in both the trabeculæ may dilate and extend towards the serous coat forming little pockets. These diverticula are of clinical importance, as they greatly complicate the treatment of cystitis.

Also, *sacculation of the bladder* is a most serious complication in all operations upon the viscus; it is unfavourable in lithotomy, and in lithotrity is a source of danger as well as a cause of failure. The reason is easily found.

As a rule, sacculated bladder is met with in cases of long-neglected retention of urine, from chronic stricture, enlarged prostate, or other obstruction to the exit. This not only calls for increased power of expulsion, which is met by hypertrophy of the muscular coat, but also means greatly increased tension of the urine within the bladder during micturition. The hypertrophy of the muscular bundles is easily seen with the cystoscope; they raise up the mucous membrane in elongated ridges, interlacing with one another. But while the muscular trabeculæ form a prominent network, little spaces are left between them where the mucous membrane is badly supported. Consequent upon high tension of the urine during micturition, the inflamed and softened mucous membrane is forced outwards, and ultimately becoming free of the muscular coat, a sac projects beyond the wall of the bladder.

This adventitious sac, having no muscular wall, is not emptied during micturition; the urine in it decomposes and inflammation follows. There is a rapid proliferation of soft connective tissue which steadily yields to the internal pressure, and ultimately the secondary sac may assume proportions equal to that of the bladder from which it originated. The sacs may be numerous but small, or they may be few in number and large in size. In both circumstances they may

become the depositories of decomposed urine, which cannot be washed away or spontaneously evacuated.

To the surgeon the danger and difficulties associated with sacculated bladder are numerous. The retained decomposing urine produces toxic effects very prejudicial to the welfare of the patient, in view of an operation. Not only cystitis, but even peritonitis, may be induced as a result of even trivial interference with the bladder, and when the walls of the sac are attenuated rupture of its wall may be readily caused by undue distension by urine or by fluid used in washing out the bladder.

Instances are recorded in which the diverticulum has protruded into the vagina and contained a calculus which was removed, the sac excised, and the neck ligatured with a successful result, and the writer has published several cases where calculi have been completely hidden for a time in vesical diverticula. During the operation of lithotrity fragments of the stone are very liable to find their way into these recesses, where their removal becomes impossible by any process of washing. On account of the decomposition and stagnation of the urine large-sized calculi are liable to form, or a vesical stone may drop into the pouch and escape detection with the sound or even with the cystoscope.[4]

Atony of the bladder.—The power of the bladder to expel urine may be diminished or lost as a result of atrophy of the muscular coat, and the walls of the organ become expanded, thinned, and weakened. This may occur in the absence of any mechanical obstruction, and is due to vascular, myogenic, neurogenic, or toxic causes—most commonly the latter. It is frequently met with in elderly men, and is liable to be attributed to the prostate, if that organ is at all enlarged, even although the gland is not causing obstruction. They are veritable prostatics without prostatic obstruction. The bladder is void of trabeculæ, but its wall is sclerosed and the muscular elements degenerated.

Pericystitis may arise in connexion with diverticulum of the bladder and may be due to exudation of the contents of the viscus through its attenuated walls or to rupture of the pouch. The exudation may become absorbed, but as a rule it goes on to suppuration. The attack is associated with fever, pain, and often with retention of urine caused by displacement of the bladder, the result of pressure.

Palpation detects a swelling above the symphysis, or posteriorly through the vagina, or in the male through the rectum, and when the bladder is emptied by catheter the swelling and percussion dulness persist. When the lower aspect of the bladder is involved the exudation may obscure the anatomical outline of the prostate or of the seminal vesicles, and, when a sound is passed into the bladder the viscus is found to be lifted away from the rectum. In some instances the perivesical abscess may rupture into the intestine and a fistula becomes established. When this happens the urine will contain fæcal matter and gas will find its way into the bladder.

The renal complications of cystitis are always serious and frequently the immediate cause of death. The organisms are, to begin with, parasitic to the bladder alone, and they or their toxins are not absorbed into the body of the host in sufficient quantity to cause serious disturbance until some other agency supervenes—a mixed infection occurs, the patient is attacked by some debilitating disease such as influenza, he has been called upon to retain urine beyond the normal limit, or he has sustained an injury. Any of these, among many other causes, may be the determining influence in exciting a sudden extension of the infective processes.

Infection may pass upwards along the lumen of the ureter, or by the lymphatics, and induce secondary inflammation of the pelvis or of the parenchyma of the kidney. Very acute pyelonephritis may follow upon infection from old-standing disease of the bladder, so that mild sepsis of the lower portion of the urinary tract, although of no immediate danger in itself, by threatening the kidney it is a continual menace to the life of the patient.

(To be concluded.)

Sir George Beatson, K.C.B., will deliver a lecture at the Medical Graduates' College and Polyclinic on Tuesday next, Feb. 27th, at 5.15 P.M., on "Treatment of Acute Appendicitis: When and How to Operate." The lecture will be open to all members of the profession.

THE INTESTINAL FLORA.

BY A. DISTASO, D.Sc.,

DEMONSTRATOR OF BACTERIOLOGY IN THE ROYAL INSTITUTE O PUBLIC HEALTH.

I. COMPOSITION OF INTESTINAL FLORA IN NORMAL STATE.

VERY little is known of the composition and of the functions of the normal intestinal flora of man. I propose here to give a brief summary of the results of my researches, which extend over a period of three years, and the details of which will appear soon *in extenso*.

The practical result which I aimed at was to enable one by the simple microscopical examination of fæces to recognise the predominance of one micro-organism or another, and thus to be able to form an opinion of the way in which the flora acted. Here it is better to deal with groups, since many organisms of the intestinal flora closely resemble each other in their biological properties.

The following are the chief types which I have marked out :—

Chief Types of Intestinal Flora.

A. *Gram-negative Bacilli.*

1. *B. coli group* (B. coli Esch., Durham, B. lactis aerogenes, B. acidi lactici, B. paracoli, B. proteus, B. pyocyaneus, &c.).
2. *B. variabilis group* (anaerobic bacilli with round extremity).
3. *B. rigidus group.*
4. *B. thetaiotaomicron group* (bacilli very polymorphic, with elliptical form).
5. *B. praecutus group* (bacilli swollen in the middle and pointed at the extremities).

B. *Gram-negative Cocci.*

These can be classified under three groups :—

1. *Sarcina citrea group*, very common in the mouth and in the fæces, similar in appearance to the gonococcus.
2. *Diplococcus orbiculus group*, which are strictly anaerobes.
3. *Parvulus group*, strictly anaerobic small cocci.

C. *Gram-positive Bacilli.*

1. *B. acetogenes group.*—The greater number of the Gram-positive bacilli belong to this group. The B. acetogenes β is the chief representative, since the B. bifidus and acetogenes α are very rare in the fæces examined in London.
2. *Streptobacillus group.*—This microbe always exists in the intestinal flora.
3. *Diplob. acuminatus group.*—An anaerobic bacillus. It produces butyric acid.
4. *B. perfringens group.*—An anaerobic microbe. It produces enormous quantities of butyric acid.
5. *B. œdematis maligni group*, with the B. sporogenes (Metchnikoff).
6. *B. rodella group.*—Anaerobic group of very long bacilli.
7. *A lemon-shaped bacillus*, which is stained by iodine and is described by the author as being a butyric acid producing microbe. It has not yet been obtained pure.

D. *Gram-positive Cocci.*

1. *Enterococci group*, in chains, less frequently diplococci.
2. *Small cocci group.*—Are also to be seen corresponding in size to the coccus Banani, to the staphylococcus pyogenes, and to the staphylococcus asaccharolyticus.
3. *Streptococcus intestinalis group.*—This group contains the streptococci of Hirsch-Liebmann.

In addition three kinds of *spores* are to be found.

1. Oval spores, rather large, which may belong to the B. sporogenes and to other
2. Round spores, which may belong to the B. putrificus (Bienstock-Tissier) or to the bacillus of Rodella and to the B. alkaligenes anaerobicus.
3. Very small spores, strongly refractile, belonging to the B. perfringens.

These species may be identified by simple microscopical examination.

It is very evident that, as the nitrogenous substances diminish, the bacteria in the intestine become more abundant and the species more numerous. This fact is difficult to explain if we do not consider a factor of great importance—intestinal stasis. When this is present the conditions which obtain in the colon may be compared to those in the test-tube. Another factor in the large intestine is the absence of sugars. I have shown in my paper on intestinal putrefaction that the large bowel does not contain either albumin or peptone. It contains only derivatives of the latter substance, and the microbic flora present in the large bowel must adapt itself to these surroundings. We find on studying the biology of the organisms that it is the indol-forming organisms which predominate.

From this point of view I have classified the intestinal microbes as follows:—

A. *Non-Indol-forming Organisms.*

1. *Amylolytic organisms.*—They produce sugar from starch.
2. *Saccharolytic organisms.*—We divide this group according to the principal acid found in the culture—
   (a) *Acetogenic.*
   (b) *Butyric.*
   (c) *Lactic-acid-producing*, but this group does not exist in the intestinal flora.
3. *Asaccharolytic organisms.*—These do not touch the sugars with the possible exception of a very slight action on glucose.
4. *Gelatinolytic.*—These dissolve gelatin, but they do not act upon coagulated albumin.

B. *Indol-forming Organisms.*

1. *Amylolytic.*
2. *Saccharolytic.*
   (a) *Gelatolytic*; (b) *Peptolytic.*
3. *Asaccharolytic.*
4. *Proteolytic.*

This classification allows us to group the organisms according to their functions—that is, those which produce indol and its congeners and those which have not this property. Moreover, we are enabled to include in definite groups those organisms having similar biological properties with respect to their functions *in vivo*. This grouping leads to the important fact that the organisms of groups having similar biological properties can replace one another, which I have found to occur in changes of nutrition and in pathological conditions. (In the human flora I have never succeeded in finding organisms which act upon cellulose. In fact, I do not believe any exist, for on inoculating tubes with filter-paper (Berzelius) in a saline medium the paper is broken down, but not dissolved.[1])

The organisms mentioned above are constantly present in the intestinal flora of adults in the normal state; they are also found in the first stage of intestinal putrefaction. It may be objected that this flora contains organisms capable of hindering putrefaction—for instance, the B. coli. This, however, is difficult to conceive, since in the colon there are no sugars, and therefore these microbes lack an essential requisite in order to exert their beneficent action. I explain more fully in another paper the value of this fact with reference to the intestinal flora.

The flora of the normal adult, therefore, is certainly harmful, and, far from defending the organism against infection, it may be said to help it.

It appears from the peculiar grouping of the microbes found in the colon that the digestive functions as carried out in the large bowel are different from those that take place in the rest of the intestinal tract, because in the colon indol and other bodies belonging to the heterocyclic and aromatic series are elaborated and absorbed. These bodies, when absorbed, severely tax the functions of the body and therefore of the liver. This fact may throw some light on the etiology of diseases of the liver.

Moreover, these bodies elaborated by the normal intestinal bacteria are not able to induce peristalsis, in which they differ from those produced by the intestinal flora of breast-fed babies; on the other hand, they may have an inhibitory action on intestinal peristalsis or may even irritate the mucous membrane.

These facts lead to the conclusion that the normal flora in adults, besides exerting no beneficent action, may be of itself, under certain conditions, distinctly dangerous, predisposing to constipation or diarrhœa. This I propose to prove in the following remarks.

II. On the Intestinal Flora in Constipation.

In the foregoing observations on the intestinal flora of normal adults I have established the fact that the indol-forming organisms are the most prominent and therefore they cannot be considered as harmless.

The researches which I have undertaken, and the details of which will shortly be published, demonstrate the relations between the intestinal flora and constipation on the one hand, and on the other the relations between the processes which go on in the large intestine and the resultant auto-intoxication. From this it follows that since constipation gives rise to these consequences, and since these poisons are elaborated in the colon, the exclusion of the viscera must be followed by the disappearance of constipation and of the resulting intoxication.

I have been twice sent over to England by Professor Metchnikoff in order to investigate from this point of view the patients operated upon by Mr. W. Arbuthnot Lane,[2] but before discussing the results arrived at it is necessary to establish what takes place in the intestine in cases of constipation. Here are briefly the results of my researches.

The composition of the flora of a constipated man is quite peculiar, the following being the chief features: (1) the fæces are dry and somewhat like goats' excrement; (2) the total number of bacteria is less than normal; (3) Gram-negative forms are almost entirely absent; and (4) spores are very abundant.

In view of these observations it was natural to ask what takes place in the intestine in constipation. To answer this query I have carried out the following experiments. Portions of normal fæces were incubated at 37° C. To some of these sterile water was added, whilst others were incubated without addition of water. In the last case the Gram-negative bacteria died off, spores became abundant, and Gram-positive bacteria could be seen here and there. The features of this flora are identical with those of the flora of constipated persons. The same results were observed in the fæces that were kept moist with the addition of water, only they took place more slowly. Thanks to the kindness of Mr. Lane—who furnished me with three cæca—I have been enabled to ascertain that the same conditions obtain in the cæcum.

The bacteria therefore existing in the proximal part of the large intestine are identical with those to be found in the distal part, but in the latter they are far less abundant and more spores are present. Hence I conclude that a process of putrefaction goes on in the intestine of constipated persons which is similar to that which is to be observed *in vitro*. This demonstrates clearly that the phenomena that are going on in the large intestine in constipation are nothing but putrefaction *in vivo*.

The effects of this putrefactive process on the organism are easily understood. Not only is there intoxication by the products of bacterial growth, but the disappearance of the bacteria indicates a process of autolysis, the products of which when absorbed cannot fail to be harmful.

It now remained to ascertain the primary cause of constipation. No better material can be found than that offered me by Mr. Lane.

I shall not deal here with the publication of Lane and Chapple, nor shall I discuss whether the exclusion or excision of the large bowel is admissible from the physiological point of view. I only want to point out that the cases operated on by Mr. Lane and the experiments carried out on dogs by Albu both demonstrate plainly that this operation is possible, and that both men and animals can do without the large bowel.

Before going on with this subject let us consider the fæcal flora of patients without the large intestine. The following results are compiled from a study of 36 cases. In many of these cases the flora has been investigated both before and after the operation. Before the operation the flora of these patients was typical of constipation, as I have briefly described above. After the operation the flora suddenly changed, and those microbes which I have called acetogenes (B. bifidus, B. acetogenes α and β) became predominant, thus resembling the flora present in infants. It is evident, therefore, that the change in the intestinal flora caused by the exclusion of the large bowel is such that, assuming that the ill-effects of constipation are due to bacteria associated with this condition, these effects will be abolished by the operation.

The following conclusions may therefore be drawn: (1) That constipation and the resulting intoxication are caused by the intestinal flora; and (2) that the large intestine is the seat of this process.

It is necessary now to determine how constipation occurs. Doubtless the products of the intestinal bacteria, by increasing secretions inhibiting the submucous plexuses, give rise to stasis. The accumulation of fæces in the colon causes the viscera to fall downward, dragging on the organs which are attached to it. The ileum especially is affected, so that it may be almost occluded, or the ileo-cæcal valve may become inflamed, and thus the passage of fæces be further impeded.[3]

The observations made by Lane extending over a long

[1] These tubes show the same action as our *B. cellulosæ disagregans* in pure culture (Société de Biologie, 1911).

[2] THE LANCET, April 29th, 1911, p. 1130.

[3] THE LANCET, Dec. 2nd, 1911, p. 1540.

period in which he had the opportunity of seeing the organs *in situ*, are conclusive. In his book[4] he describes how the ileum in its junction with the colon becomes kinked, and the passage of fæces through it is impeded. In this way the stasis starting in the colon extends to the small intestine.

These observations made at the operating table were subsequently confirmed *in vivo* by means of the X rays by Gottwald Schwarz,[5] who observed that in constipated subjects the fæcal matters remained in the lower part of the ileum almost eight hours, and that the movements of the large bowel, although increased, are irregular and inconstant in direction, so that the fæces are pushed up and down for some time. This is the cause of the drying up of the fæces in constipation, the intestine exerting an action similar to that of a shaking apparatus.

All these observations confirm the assertion that constipation is due to the intestinal flora which causes the retention of the fæces in the large bowel for a long time. These undergo putrefaction. Hence the production of the soluble poisons on the one hand, and the extraction of the poisons retained by the dead microbes on the other give rise to auto-intoxication. All these phenomena are removed by the removal of the large intestine. Therefore there is no doubt that the seat of constipation is in the large bowel, and that the intoxication occurring in a constipated person is the result of the activity of the microbes of the intestine.

THE ILEO-CÆCAL VALVE.

BY DR. OSCAR KRAUS,
KARLSBAD.

SOME 20 years ago Cantani in Naples and others very strongly advocated the so-called enteroclysis for the treatment of certain intestinal disturbances, some of which had their seat in the small intestine. Bearing in mind the old French denomination of the ileo-cæcal valve as the "barrière des apothicaires," I desired to ascertain positively whether the supposition of olden times, that an enema could not pass that valve, was right, or whether it was possible that, as Cantani asserted, medicated liquids could by a simple enema be introduced into the lower part of the ileum or small intestine. This problem led me to a series of researches,[1] the results of which were confirmed by different anatomists (Toldt, Zuckerkandl, and others).

It cannot be a matter of indifference to the economy of metabolism whether, if I may be permitted the metaphor, the small intestine be closed towards the large intestine by a Chinese wall with an outlet, or whether between the two exists the policy of the open door. It is remarkable that 300 years after the discovery of the ileo-cæcal valve such contradictory suggestions as to its function and action are to be found in literature.

Although the historical part of the question is very interesting and shows how far advanced in detail was the knowledge of the old anatomists, Varolius, Bauhin, Van Tulp, Fallopius, Fabricius d'Aquapendente, and others, I refrain from entering upon too minute a quotation. However, I cannot help quoting a passage from an anatomical lecture by Archangelus Piccolomini, printed in 1586,[2] in which the question of the competency of the valve is so well made out that there is really little to be added. It runs as follows:—

Valvae tres, quemadmodum in corde, ad caecum intestinum sunt additae, tanquam ostiola quaedam deorsum spectantes, hunc in finem, ut materiam in intestinis gracilioribus conclusam deorsum illabi sinant, illapsam autem in crassiora impediant, ne sursum resilire possit. Proinde harum valvularum interventu, quicquam in crassioribus intestinis, sive stercus sive putridus flatus exsiterit, prohibetur, ne in violentis abdominis compressionibus in tenuiora nobilioraque intestina possit refundi ad praepediendas nobiliores naturae functiones. Has autem valvas caeco additas observatione deprehendes, si colon inferne impleveris aqua, illudque sublime suspensum teneas, cernes nihil prorsus aquae valvas illas perfluere et in gracilliora intestina subire. *Sed quid de aqua dico?* cum si rectum intestinum *aëre ac flatu*, qui longe aqua est penetrabilior, sufflando impleveris, ne minimum quidem flatus erumpere videbis a colo et caeco in ileum, *tam arcte claudunt valvae illae. Imo, si pugno premas colon, potius aliquid disrumpetur*, quam valvae illae cedant flatus ascensui in gracilliora intestina.[3]

Other literature to similar purport is quoted in my publications before referred to.

The most difficult thing in making these anatomical preparations is to get the material unaltered and without tearing it. Unfortunately, these parts of the bowels are to be obtained only *in the course* of post-mortem examinations, when those who assist the operator are apt to pull upon the intestines and thus destroy the natural conditions. This of course renders them useless, and it cannot be pointed out too strongly that the cæcum and the adjoining part of the ileum must be cut out most carefully immediately after the opening of the abdominal wall, before any other manipulation takes place. After the resection of about 8 inches of the colon (see Fig. 1) this gut is closed by means of a ligature. The ileum is not ligatured. If, then, with a double bulb syringe air is insufflated from the ileum into the colon—that is, in a direction opposite to that in which the insufflation was carried out by Piccolomini—it will be found that this air does not escape in the most diverse degrees of fulness of the gut, even though the ileum be not ligatured. This means that the valve closes quite tightly in a passive way.

After having carefully removed fat and mesenteric elements and looking at the front of such a preparation (Fig. 1), the peculiar disposition of the anterior tænia is striking; it describes an arch with its concavity opening upwards and inwards, corresponding to the inclination of the axis of the cæcum towards the colon. In this part of the gut there are constantly found three haustra which I have called *haustrum cæcale*, *haustrum ileo-colicum*, and *haustrum coli primum*, following the direction from below upwards.

In the intestine represented in Fig. 1 it appears that the *haustrum ileo-colicum* is covered by the two neighbouring haustra to such an extent that only a small triangle of it is visible, the base of which is formed by the tænia, the apex looking towards the ileum. *This configuration is to be seen in all bowels with a competent valve.* Looking at the back of the gut the peculiar direction of the tænia also strikes one. It rises perpendicularly from the region where the ileum enters the cæcum. At this very spot I found a band of longitudinal muscle fibres, from 0·08–0·16 inch in length, diverging from the tænia and forming a small bridge passing behind the ileum and over the two adjacent haustra. I have found this band regularly in all guts examined and have called it *habenula cæci*. Toldt[4] misapprehended its nature. We shall still have to deal with it. By removing fat and blood-vessels from the sulcus under this bridge it is possible to pass a probe under the latter (Fig. 2).

In order to ascertain how a competent valve would appear when seen from the inside I introduced and fastened by a ligature a sort of window in the wall of the gut on the side opposite to the valve so as to be able to inspect it. This method has since proved satisfactory for the purpose of demonstration. (Zuckerkandl in his Topographical Atlas and others have copied it.) Fig. 3 shows the view of such a valve as seen through the above-mentioned window. The ileo-cæcal valve represents, according to its shape, an invagination of the end of the small intestine into that part of the bowels where the large intestine begins a sort of duplication, which bulges into the cavity of the cæcum. Its opening forms a button-hole-like fissure, produced by the apposition of two falciform folds. The upper fold is very long, similar to a real plica sigmoidea. Its ends are called frena Morgagni; the lower one is much the shorter, semicircular,

[3] Three valves, as is the case in the heart, are appended to the cæcum, like little doors looking downwards, in order that they may allow matter confined in the smaller intestine to pass downwards, but prevent that which has passed into the greater (bowel) from returning upwards. Therefore, by the intervention of these valves whatever, whether fæces or putrid gases, may be in the larger intestine, is prevented from being forced back during violent compression of the abdomen into the smaller intestine to the hindrance of the higher functions of nature. But in order to observe these valves attached to the cæcum, if you fill the colon from below with water and hold it suspended on high, you will see that none of the water flows backwards through the valves. But why do I speak of water? when if you fill the rectal intestine by insufflation with air and flatus, which is far more penetrating than water, not even one jot of flatus will you observe to escape from the colon and cæcum into the ileum, so tightly do those valves close. On the contrary, if you squeeze the colon with your hand something will break, rather than those valves will yield passage for the ascent of flatus into the small intestine.

but as long as the opening of the valve. According to Luschka, the lips of the valve consist of the mucous membrane and of the circular fibres of the muscularis. Further, according to his statement, the serosa does not participate in the invagination, and also the longitudinal fibres of the small intestine do not enter the substance of the valve, but getting thicker, pass over into the wall of the large intestine. According to Toldt,[5] however, both the longitudinal fibres of the tænia and those of the ileum reach the *edge* of the lip of the valve. My histological researches confirm Toldt's statement. The microscopical preparation clearly shows that the longitudinal fibres reach the edge of the valve (Fig. 5).

As can be seen from the diagram, the ileo-cæcal valve is a real valve, which allows the passing over of the contents towards the large intestine, but prevents passage in the opposite direction. It closes perfectly passively, even in the anatomical preparation—that is to say, without muscular action. It may be compared with Bunsen's indiarubber valve, a "lip-valve," as used in chemical laboratories. It consists merely of a small closed indiarubber tube, forming the outlet of the glass tube through which the gas passes. A very small longitudinal cut or slit is made with a sharp razor into the rubber, which consequently permits the gas to escape. To a recurrent gas stream, however, the lips of the slit will be compressed and will close still tighter.

What occurs if we continue to force air into the gut without heeding the tension of the bowel? That which Piccolomini describes—namely, "ut aliquid disrumpetur." We find that: 1. The colon tends to stretch straight, the curve or bending of the cæcum having partly disappeared, a condition shown by the straighter direction of the anterior tænia. 2. In this forced stretching the shortest, that is the inside, tænia has been ruptured. 3. The haustrum ileo-colicum now lies quite free and is no longer covered by the haustrum cæcale and haustrum coli primum. 4. On the posterior aspect we see that the upper insertion of the habenula has been torn off, the habenula itself having retired downwards. 5. The connective tissue forming the normal adhesions between the anterior part of the upper wall of the invagination between ileum and colon have been torn over an area of the size of a halfpenny. 6. By accurate measurements I have been able to demonstrate that the upper lip had thus been shortened and retracted from the lower one, that the invagination had disappeared at the point in question, and that the valve is no longer competent (Fig. 4). Its lips are gaping, as can be seen through the window inserted in the bowel. *I must especially emphasise that all these, and only these, changes take place regularly*, as often as the insufflation passes a certain limit.

The sketches of Figs. 6 and 7 demonstrate the mechanism whereby the valve closes.

In competent valves the fibres pull with equal force from all sides unto the base of the funnel with a force greater in proportion to the extent to which the bowel was inflated. The adhesions between cæcum and ileum resist this pulling so long as the lips of the valve remain united. If, on the other hand, the valve is torn, the force of the insufflation works (as shown by the arrows in Fig. 7) straight on the upper border of the lip, pulling it away from the lower lip, and the valve is no longer competent. Now, in my opinion, which is also shared by Toldt,[6] it is the very habenula which protects the adhesions between ileum and cæcum from being torn.

Among the bowels examined by me I have found 12 the valves of which were not competent. I am quite aware that the material used in my investigation, some 150 cases, is not very extensive; but it is very difficult to get complete unlacerated guts from the post-mortem room. Anyhow, according to my findings the competency of the valve must be considered a normal condition so long as control investigations fail to prove the contrary.

The bowels with *incompetent* valve showed the following particulars: (1) colon and cæcum were very wide in all of them; (2) the colon was quite straightened (straight anterior tænia); (3) the three haustra lay in apposition, the haustrum ileo-colicum not covered by its neighbours. Very often no sharp limit existed between the three haustra. Thus we find in bowels with insufficient valvulæ coli the same changes as in incompetency artificially produced.

In new-born children the valve is incompetent, and we must surmise that competency is attained in the first years of life. In the post-mortem on a boy 5 years of age I found the valve competent. Whether in the cases of incompetency quoted we have to deal with a persisting infantile condition or with acquired incompetency I cannot say.

These are the anatomical results of my investigations which I may be permitted to sum up in the following conclusions.

1. In a gut removed from the cadaver the valve shuts up gas-tight by passive action. That is the normal condition.

2. It is possible to destroy the competency of the valve by excessive insufflation of the colon. The changes which are thus produced are typical.

Until now we have dealt with the conditions of the valve in a gut *removed from the cadaver*, and we have seen that under merely mechanical conditions the valve is competent and closes gas-tight in a passive manner. But we were only speaking of the way the valve closes. Logically we have now to ask: How does the valve open? Does this occur in a merely passive manner—that is, exclusively by the inner pressure of the contents? Unfortunately, we cannot get an answer to this question except by inspection, for this could only be seen *intra vitam*. Moreover, experiments on animals fail to help us to resolve this question, for in most animals used in experimentation, although they possess more or less distinct thickening of the circular muscle fibres, we fail to find a really competent valve, not only in the highest anthropomorphs, but even in new-born babes. And there is not only a great morphological but also a functional difference between a simple ring-muscle and a complete and competent valvular apparatus. The first stands open and may contract, as the other circular fibres of the gut do, while the intestinal valve of the adult man closes perfectly by passive means. These reinforced circular fibres are to be seen in the guts of dogs, where the rudiment of a valve scarcely projects into the lumen of the bowel. In the intestines of the dog the part corresponding to the human ileum passes directly over into the colon, and the relatively large cæcum forms a special appendage. In murines (mouse, field-mouse), in rabbits and hares, and so on, the condition is similar. In most of these herbivora the cæcum is large; in the hare about ten times as big as the stomach. Although they do not shut there exist sometimes two valves between the cæcum and colon, but none between the small and the large intestine.

It has already been mentioned that *intra vitam* we have to deal not merely with mechanical but with bio-mechanical conditions, in which not only the turgor of the intestinal wall and the tonus of the muscles participate—conditions which must have a still better influence on the tight closing of the valve—but in which the innervation also has to be taken into consideration. V. Zessl has shown that the sphincter vesicæ opens not merely in a passive way, following the pressure of the detrusor, but actively also by irritation of the nervi erigentes, and even after the detrusor has been cut through. V. Frankl-Hochwart and Froehlich succeeded in relaxing the sphincter ani by cortical irritation. Taking these statements into consideration, we may suppose by analogy that this shutting or closing apparatus, also consisting of circular and longitudinal muscles, might be opened by nervous action; that it probably is opened in consequence of the contact with the chyme, or, to use a technical term, reflexly on short circuit, though it generally closes quite mechanically in the same way as the bladder and anus do.

Of course, this refers only to physiological conditions. For it will not do, as Hyrtl has done, to take the vomiting of fæces which occurs in ileus as a proof of the normal competency of the valve. Ileus is certainly not a physiological condition, and any physician who has had the opportunity of observing a case of ileus will surely admit that the organism is struggling against the obstacle with an amount of strength surely sufficient to produce all the changes that I have described above.

But, as has been mentioned, it is only possible to draw these conclusions by analogy, for we are not able to ascertain the facts by experiment on animals. We know, however, of a simple observation which is as demonstrative as an experiment would be. This is the classical case communicated by Nothnagel in 1884, in his well-known contributions to the

[5] Ibid.

[6] Besides that, the mesenteric covering helps, by tight fibres which retain the curve of the cæcum *in situ*, to keep the valve competent.

physiology and pathology of the bowels. In one of his patients ileus had been protracted during nine days. Some hours before death a very small quantity—if I remember correctly 8 oz.—of a coloured NaCl solution had been injected per anum, and it was possible to detect the coloured liquid about 15 inches above Bauhin's valve. This experiment shows quite distinctly that antiperistaltic movement can arise under pathological conditions.

How can we utilise this experiment to solve the question of competency. In a double way. In his case Nothnagel had to deal either with a valve that had been originally incompetent, or with one that had become incompetent in the course of the ileus.

Chance plays a great part in medicine. I remember that when preparing the fresh anatomical specimens for a demonstration before the Society of Internal Medicine in Vienna, as chance would have it, the first valve I came on was incompetent; yet they are by no means frequent as that might seem to suggest. So it is quite possible that Nothnagel's valve also was originally incompetent. But further, Nothnagel relates in a most illustrative way the treatment that had been applied before his arrival—enemas of iced soda-water, Hegar's injection of two quarts of liquid, and so on. Taking into consideration that the whole colon can scarcely take a little over two quarts on an average, we cannot be surprised if the valve was torn by such proceedings, especially by hyper-extension.

I am very sorry that since my first paper appeared this quite harmless, but very illuminating, experiment of Nothnagel has not been repeated. I am sorry that it has not been repeated in invalids without ileus, that it has not been repeated in patients with intestinal fistula, and that the changes as described by me have not been observed. By so doing one would surely have succeeded not only in throwing light on this subject but also in getting indications as to the limits of insufflation that physiological conditions will allow.

Different authors have tried to bring into connexion the function of the ileo-cæcal valve with the movements of the bowels. Anyone who has devoted himself to the study of peristalsis will surely admit that this is a very difficult problem, and I must confess I am not brave enough to get into a scrape unnecessarily; and I do not see any necessity for it, for the closing of the valve has but a very loose connexion with the intestinal movement.

There has been much discussion concerning the purpose and utility of the valve and as to what were the aim and idea of its action. Several authors have asserted that scientifically we are not entitled to claim a special utility for any organ and consequently not for the ileo-cæcal valve. But this view cannot stand a serious discussion. Even Darwinism deals with teleology: the great doctrine of adaptation, mimicry, and other phenomena are nothing else in principle than teleological. But concerning the law of adaptation it is stated that "the function creates the organ." Seeing by phylogenetic as well as by ontogenetic studies that there is a steady transition from the tube with open communication between small and large intestine to the complicated apparatus of an entirely competent valve, we must say that the existence of this organ is entirely due to the fact that its function has been established by degrees and *vice versâ*: if the valve does exist it must consequently have got a function—that is, a purpose. In common language these two words are used for the same thing.

But as far as my opinion goes it will be not the anatomists but the chemists who will tell us what is the purpose of the ileo-cæcal valve. Anyhow, I find, to my thinking, a striking proof of the normal competency of the valve in the intestinal chemism. It is commonly known that of late years a long series of so-called "fistula analyses" has been carried out, and this by most reliable authors, such as Ewald, Nencki, Zakowski, and others. Anyone who has at any time been occupied with anatomical research on the gut knows of the penetrating smell of the products of decomposition of the albuminoids, an odour which will cling to anything, the hands, clothes, or instruments. But none of these authors could find in the small intestine appreciable quantities of these products of decomposition—viz., phenol, scatol, indol, mercaptan, and so on. I can only explain this by the fact that the valve is competent as regards the passage of gas, though only in so far as normal conditions are dealt with, for we know well that in pathological forms of digestion, especially in anomalies of acidity in the stomach and of the secretion of bile, putrefaction (decomposition of albuminoids) can take place in the small intestine. But that has, as stated, nothing to do with normal physiological conditions.

Up to date nothing has been discovered concerning the possibility of opening the intact valve through its innervation. Histological conditions do not permit us to exclude this possibility, but the physiological statements, as made for other sphincter muscles, allow us to assume it as probable. It is not probable that the intact valve can be opened from the large intestine; and the old quotation from Piccolomini still holds good: "Klyster penetrare non potest in graciliora intestina."

A CASE OF PYÆMIA TREATED WITH SPECIFIC ANTISTREPTOCOCCUS SERUM.

BY C. W. G. BRYAN, F.R.C.S. ENG.,
LATE HOUSE SURGEON, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, LONDON.

THIS case appears to me to be worthy of record if only on account of the rarity of pyæmia as a complication of the Lorenz operation for congenital dislocation of the hip.

The patient, a girl aged 2 years 3 months, was admitted to the Hospital for Sick Children, Great Ormond-street, on July 5th, 1911, under the care of Mr. H. A. T. Fairbank, suffering from a congenital dislocation of the right hip. The deformity was very slight. She had commenced to walk at the age of 1 year 6 months. She was a well-nourished, healthy child, without any sign of disease other than the hip deformity.

On July 6th an operation was performed. The patient was anæsthetised with chloroform followed by open ether. The skin having been washed with ether soap and powdered with boric powder the hip was very easily reduced; the adductor muscles were not torn through, and very slight violence was necessary to obtain full abduction. No abrasion or immediate bruising of the skin was caused. On the 8th some bruising in the adductor region appeared, distinctly less than in the average case. Except for slight variation in temperature, which rose to 100° F. on the 14th and to 102° on the 15th, nothing abnormal occurred until the latter date, when œdema and tenderness were apparent over Scarpa's triangle, the œdema involving the right labium majus. A small abscess under the deep fascia in the adductor region was opened and drained, about half an ounce of thin pus being evacuated. The temperature at night was 101°. On cultivation of the pus a pure growth of streptococcus was obtained.

On the evening of July 16th the temperature rose to 104°. The plaster-of-Paris splint having been removed, the abscess was again opened up and found to have tracked down the thigh. Two further incisions were made and very thorough drainage was established. The wall of the abscess was carefully examined and there was no sign of deep extension. The hip-joint itself seemed normal, with no suspicion of fulness or other sign of suppuration. For the next ten days the temperature was about 103° at night and 100° each morning. The patient became extremely toxæmic and rapidly wasted. The wound showed no sign of granulation, and the pus which was discharged was small in amount and contained few leucocytes. On the 26th the left hip-joint filled up with pus and was opened and drained posteriorly. On the 29th the right hip-joint became affected. Both joints were freely opened and drained in front and behind. The patient after the operation was very collapsed, but rallied somewhat after treatment with subcutaneous saline and stimulants. On the 30th a subcutaneous abscess in the left malar region was incised.

On August 2nd suppurative tenosynovitis of a finger developed and the sheath was opened. On the 3rd an acute abscess developed under the left trapezius, tracking under the scapula towards the clavicle. The child was now too ill for general anæsthesia, so after injecting novocaine locally I drained the abscess with three incisions.

From July 21st to August 2nd streptococcus vaccine was administered; at first two doses of a stock polyvalent vaccine, later a specific vaccine which was administered

daily in doses of 250,000 to 1,500,000. I was unable to observe any very definite effect from the vaccine. On July 15th 10 c.c. of a polyvalent antistreptococcus serum was administered; this was repeated on July 19th and August 4th. No beneficial effect was evident.

In counterdraining the abscess on August 3rd I was careless enough to abrade my own finger. Very acute cellulitis supervened, and the finger was incised by Mr. V. Warren Low 18 hours after the accident. After another eight hours, as lymphangitis was spreading and had reached the axilla and my temperature remained at 102°, 1,000,000 of the specific vaccine which I had prepared for the child was administered to me. My temperature immediately became normal, and the infection from this time was quite localised. Captain S. R. Douglas kindly directed my treatment by vaccine and examined the streptococcus obtained from my finger, expressing the opinion that it had the morphological character of streptococcus fæcalis.

Meanwhile the pyæmic child was apparently *in extremis*, there was no attempt at granulation in any of her wounds, and the temperature varied between 100° and 103°. On August 10th, 40 c.c. of blood was withdrawn from my median cephalic vein and allowed to clot, and on the following day 10 c.c. of serum obtained in this way was injected subcutaneously into the child. For three days her temperature was rather higher, never being above 103°, but dropping less in the mornings than it had previously done. After August 14th it gradually fell to normal. The change in her general condition was marked, as was also the improvement in the local condition of her many wounds. All the wounds began to granulate and in just over a fortnight were healed, except for sinuses in connexion with the hip-joints.

On Sept. 9th I removed a small sequestrum from the head of the left femur, and a large sequestrum consisting of the head and neck of the right femur. The sinuses gradually closed and the patient was discharged from hospital on Nov. 16th.

This case possesses several points of interest.

1. The occurrence of pyæmia after the Lorenz operation is very rare. Where suppuration occurs in the hæmatoma produced by the operation, as a rule severe violence has had to be employed in the reduction, abrasions are frequently present, and the children have been generally weakly.

2. On August 11th what amounted to a specific anti-streptococcus human serum was injected subcutaneously. The fall of the temperature from this time was gradual, but the child's general condition showed marked improvement within a few days, and the wounds, which so far, over a period of nearly a month, had shown no sign of granulation, began to heal. I know of no record of the previous use of immune human serum in similar circumstances.

3. In the treatment of myself it was possible to use a specific vaccine within eight hours of the incision of my finger, the vaccine being that which I had previously prepared from the child's streptococcus. Eight hours is too short a time for the preparation of a vaccine, and I do not suppose that an acute infection has been treated by a specific vaccine so early.

I desire to express my thanks to Mr. Fairbank for permission to publish these notes.

Kensington-gardens-square, W.

ST. MARK'S HOSPITAL FOR DISEASES OF THE RECTUM, CITY-ROAD, E C.—The Lord Mayor of London presided at the Mansion House on Feb. 16th at the annual meeting of the supporters of this hospital. Sir Thomas Crosby, in welcoming the audience to the Mansion House, said that his knowledge of the hospital was of very long standing. More than 50 years ago he had the pleasure of knowing the founder, and in the "fifties" he assisted the staff at operations on a number of occasions. The adoption of the annual report was moved by Dr. A. W. Oxford. Sir Homewood Crawford said he thought the time had come when they might justly claim a larger grant from King Edward's Hospital Fund. The Lord Mayor pointed out that the medical officers gave their services gratuitously, and that the warmest thanks were due to them. Mr. F. Swinford Edwards, in returning thanks for himself and his colleagues, said that the aim of the hospital was to supplement the work of the general hospitals. This they did by making a very special study of fistula and its remedies. A vote of thanks to the Lord Mayor terminated the proceedings.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF PERNICIOUS MALARIAL FEVER SIMULATING URÆMIA.

BY B. N. VARMA, L.R.C P. & S. EDIN., L.F.P.S. GLASG.

THE patient was a married man aged 43 years. The family history showed that his father had had several strokes of paralysis, that his mother had been insane for several years, and that a brother (older) had recently had an attack of hemiplegia. On Nov. 26th, 1911, the patient had had an attack of coryza for which 10 grains of chloride of ammonia, three times a day, had been prescribed offhand. The condition increased in severity, and the temperatures, which was remittent, had reached 101° F. The patient then used indigenous drugs as advised by a "quack," which were of the nature of purgatives. These did him no good. He developed severe diarrhœa which troubled him much. On making inquiry into past illnesses the patient was found to have had several such attacks of continued fever which had yielded to quinine. An examination of the blood at this stage had not exhibited malarial parasites, and the differential count was normal. The condition was accordingly thought to be one of continued malarial fever—the temperature in the morning being 101·6° and in the evening 102·5. Bismuth with chalk and opium were prescribed to stop the diarrhœa, and quinine with chlorine water administered for the malarial fever. The diarrhœa did not subside under the astringent mixture. A fortnight after the onset of the coryza the patient had had epistaxis and had become mentally confused. He grew incoherent in his speech and persistent insomnia set in.

The foregoing facts, coupled with the intractable diarrhœa, led to my examining the patient very thoroughly. Physical examination revealed the following facts. Heart: apex beat in the fifth space in the mammary line; first sound normal, second sound slightly accentuated in the aortic area. Pulse 120, of moderate tension. The sphygmomanometer showed a blood pressure of 130 mm. Lungs normal; no adventitious sounds. The spleen was slightly palpable. The lower margin of the liver just felt below the right costal arch. No œdema. No dropsy. Ophthalmoscopic examination showed no retinal changes. Urine pale and clear, and showing faint traces of albumin; specific gravity 1008; microscopically, hyaline and granular casts.

The case was thought to be one of incipient uræmia on the following grounds: (*a*) A history of alcoholism extending over the last ten years; (*b*) frequency of micturition for the last two or three years, which the patient had mistaken for diabetes, the bladder being voided six or eight times in the day and two or three times in the night; (*c*) intractable diarrhœa; (*d*) epistaxis; (*e*) the urine examination showing traces of albumin, low specific gravity, with granular and hyaline casts; and (*f*) the mental condition of the patient—e.g., incoherence in speech and blank looks and persistent insomnia, &c. One-fifth of a grain of pilocarpine was administered hypodermically at once. The patient had profuse diaphoresis though the pulse got very feeble, signs of collapse intervening for which strychnine with digitalin was given hypodermically and caffein, digitalis, and strychnine in mixture. Two or three hours after the pilocarpine injection the patient got more coherent in his speech and was found to have improved in all respects, but a few hours later he relapsed into his former semi-comatose condition. The pulse being very weak the pilocarpine injection was not repeated. Hot fomentations, hot wet packs, and cupping over the kidneys were applied to eliminate the toxins. These did not bring the patient round. He got much worse; the delirium became of a raving, maniacal type, the pulse became imperceptible, and the heart sounds were barely audible. The feet and hands were cold and the conjunctival reflex was almost lost. Ten grains of veronal sodium were given for the insomnia and delirium. This failing, hyoscine hydrobromid gr. 1/100, and strychnine gr. 1/60 were injected hypodermically. Fifteen minutes after the injection the patient fell into deep sleep; the delirium ceased and the pulse got stronger. Six hours after the injection the patient awoke.

He was now quite coherent in his speech and could recognise faces. He was put on simple diapho-diuretic mixture of sweet spirits of nitre and ammonium acetate solution. The morning temperature was 100° and that of the evening 102·6°, which continued so for a week. A blood examination was again made. Pigment granules were found inside the polymorpho-nuclear leucocyte, and there was an abnormal increase of mononuclear leucocytes (large), 53 per cent. The patient was put on huge doses of quinine and the fever yielded to it readily. Subsequent examinations of the urine on several occasions showed it to be clear and orange-brown in colour; specific gravity 1025–1020. The blood pressure registered from 120 to 130 mm.

The patient has since made an uninterrupted recovery and is now quite hale and hearty.

Golaganj, Lucknow.

NOTE ON AN UNUSUAL CASE OF INGUINAL HERNIA.

BY H. M. ANDERSON, M.B. EDIN.,
SENIOR ASSISTANT MEDICAL OFFICER, WEST HAM UNION, LEYTONSTONE.

THE following case of an inguinal hernia, which was remarkable both for its size and for the nature of its contents, may prove interesting to readers of THE LANCET.

The patient was a male, aged 86 years, who died in the West Ham Union on Feb. 4th. He had an enormous left-sided inguinal hernia measuring 18 inches from the external ring to the apex, the circumference at the widest part being 36 inches.

At the post-mortem examination the following condition of affairs was found. The circumference of the neck of the sac was 11 inches. Through it had passed the greater part of the intestinal tract. The stomach measured 16½ inches from fundus to antrum pylori. Its lower half was herniated, a very marked constriction being produced by the external ring. The upper intra-abdominal portion was enormously distended and occupied the whole of the left half of the abdominal cavity. The first part of the duodenum, together with that portion of the second part proximal to the opening of the common bile-duct, was elongated, measuring 8 inches in length. The lower or proximal half of this part of the gut was in the sac; the upper or distal part extended intra-abdominally and vertically as far as the projection of the umbilicus on the posterior abdominal wall. At this level it was acutely flexed upon the lower half of the second part of the duodenum, the convexity of the flexure receiving the common bile-duct. From this flexure the gut returned to the sac. The remainder of the small intestine and the whole of the large, with the exception of a small portion of the sigmoid colon and the rectum, occupied the hernial sac. The cæcum was placed inferiorly and laterally, whilst the descending colon and splenic flexure were closely adherent to the medial wall and apex of the sac. There was a compensatory descent of the diaphragm and consequently of the liver, the lower border of the right lobe of this organ being slightly below the intercristal plane. The bladder occupied the right iliac fossa, its usual mesial position being usurped by the intra-abdominal portion of the sigmoid colon. A great increase of fat in the omenta and mesenteries and the binding together of the contents of the abdomen and sac by dense fibrous adhesions complicated the examination considerably. The testicle, very small, flattened, and atrophied, with an enlongated cord, was situate medially at a point midway between the pubis and the apex of the sac.

According to his wife's statement, the patient had had a hernia for over 50 years, the size having remained *in statu quo* for 12 years or more. For five years previously to his death the patient was bedridden. Prior to this he had been able to get about, although with some difficulty.

The capacity of the sac is unusual. It equalled, if not exceeded, that of the abdomen proper. Worthy of notice are, first, the extent to which the normal arrangement of the abdominal organs had been altered; and secondly, the maintenance of practically normal physiological functions under such circumstances. Apart from occasional attacks of vomiting and the necessity of fairly frequent use of laxatives, a very fair state of health obtained until the last.

I wish to express my indebtedness to Dr. J. Sangster Greig for permission to communicate these notes.

Leytonstone.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SURGICAL SECTION, WITH SECTIONS OF MEDICINE AND ANÆSTHETICS.

Exophthalmic Goitre.

A JOINT meeting of these sections was held on Feb. 13th, Mr. CLINTON T. DENT, the President of the Surgical Section, being in the chair.

Before the business of the meeting was proceeded with the PRESIDENT referred in suitable terms to the death of Lord Lister. The following resolution, proposed by the President and seconded by Sir ANTHONY BOWLBY, was unanimously passed by the Fellows and members standing:—

The Fellows of the Surgical Section of the Royal Society of Medicine desire to express the deep regret with which they learnt of Lord Lister's death, and to place on record their profound sense of the incalculable benefits that his life-work has conferred, not less on other branches of medical science than on surgery, and on humanity generally. They desire to convey to the members of his family their sympathy in their great loss—a loss that will be universally felt throughout the civilised world.

Dr. T. P. DUNHILL, of Melbourne, communicated a paper entitled "Partial Thyroidectomy under Local Anæsthesia, with Special Reference to Exophthalmic Goitre," which is published in full in the last issue of THE LANCET, p. 422.

Sir VICTOR HORSLEY said that he could add little to what he had contributed to the discussion at a meeting of the Hunterian Society held last year. As regards the pathology of Graves's disease, he did not entirely agree with Dr. Dunhill's classification into four classes of cases. He (Sir Victor Horsley) recognised three forms: (1) true exophthalmic goitre with watery secretion; (2) parenchymatous goitre with exophthalmic symptoms; (3) an extremely rare form in which the gland was wholly diseased, and in which he advised total removal and grafting of normal gland beneath the peritoneum. He agreed with Dr. Dunhill's view that the danger of operation was *nil;* that was his (Sir Victor Horsley's) own experience. He had had one death only, and that many years ago. It was true, however, that he had refused to operate upon three cases, and so possibly avoided a higher mortality. The high death-rates published must depend upon an incorrect estimation of the condition before operation. It was only fatal in *dernier ressort* cases. With regard to the method of operation, he had given up that by ligature of the arteries and did not consider that it cured like removal of the lateral lobe and isthmus. It was true that certain symptoms persisted afterwards, such as hurried heart action on exertion and a degree of exophthalmos, but the patients returned to work, and that was the test of surgical treatment. All his cases had been subjected for many months to medical treatment. He thought three months was long enough to wait before resorting to surgical measures. No medical treatment would cure parenchymatous goitre with exophthalmic symptoms in an adult. True exophthalmic goitre, however, often got well with faradism and rest-cure treatment. With regard to the means of producing anæsthesia, he had operated upon severe cases and always under general anæsthesia, and had seen no reason to depart from that method. He considered that the method of anæsthesia had no bearing on the prognosis. He admitted that too often an excess of anæsthetic was given. He had seen no deaths from the general anæsthetic and did not think that it should be held responsible for deaths in these cases.

Dr. GEORGE R. MURRAY (Manchester) then read a paper on the Principles of Treatment in Exophthalmic Goitre, which will be found on p. 489 of this issue of THE LANCET.

Mr. C. A. LEEDHAM-GREEN (Birmingham) said that we were at a grave disadvantage as regards operative treatment of exophthalmic goitre in England. The value of the operation had not been appreciated properly and consequently few cases were referred to the surgeon, and even these were of the severest type. It was not easy to state the mortality of the operation, for there was still great difference of opinion as to the indications for operating and as to what cases should be classed as exophthalmic goitre. At the German Surgical Congress last Easter six surgeons quoted

their mortality, which varied between 3 and 17·3 per cent., or taking the total 883 cases gave an average mortality of a little over 5 per cent. The average of many hundreds of published cases treated by conservative measures came out at about 15 per cent. The immediate result from operation was generally strikingly good. It was a difficult question to answer whether the results were permanent, for the operation had only been done systematically during the last decade, and was much more thorough now than a few years ago. Parré out of 65 cases owned to 10 or 15 per cent. failures. Von Eiselsberg, of 71 cases, reported 23 completely healed, 8 improved, 2 unrelieved. Küttner collected 85 cases; 21 were treated conservatively, 5 of these died; of the remaining 16, 9 could be traced. None were cured and only one felt better. Of the 63 operated upon, 11 died. Of the remaining 52, 37 were traced and 31 examined. Of these 33·2 per cent. were cured, 36 per cent. markedly improved and at work, 16·6 per cent. able to work, but still showed definite signs. In 13·8 per cent. no permanent benefit accrued. Of Mr. Leedham-Green's own cases operated upon, 30 in number, 3 had died: 1 from pneumonia, 1 from heart failure, and 1 some weeks later from phthisis. Of the remainder all derived definite benefit from the operation; 2 had relapsed, due to hypertrophy of the remaining lobe All the others were at work. If the operation was to have a reasonable chance of curing the patient, it must be resorted to before the vascular and nervous systems were shattered by the prolonged ill-effects of the morbid thyroid secretion. As soon as the effects of rest and medicinal treatment proved unavailing, valuable time should not be wasted before resection was considered. He had obtained the best results where he had removed most. He thought that the risk of ligation of vessels was proportionately greater than the benefit derived from it. He considered the question of the method of anæsthesia an important one, and preferred local anæsthesia preceded by a small dose of scopolamine and morphia.

Mr. J. LYNN THOMAS (Cardiff) agreed with Sir Victor Horsley that the method of anæsthesia was a very small factor in the success of the operation. He himself had had 4 deaths, among which 1 occurred after the use of novocaine, 1 was due to emotional disturbance, and 1 to pneumonia after ether inhalation, so that the kind of anæsthesia played very little part. He regarded emotional disturbance as a very important factor, and it was consequently important to keep a close eye on the patients after operation.

Dr. W. HALE WHITE said that he had investigated more than 200 cases which had been treated either at Guy's Hospital or in private practice between the years 1888 and 1909. He excluded those operated upon first. Of the remainder, he had been able to trace 49 hospital cases and 53 private ones. He had submitted his figures to Mr. Thiselton, who had kindly given him an actuarial report. The "expected deaths" among women of the ages implicated during that time were 5; the actual deaths were 8. Taking only those between the ages of 30 and 45, and excluding the few cases which occurred before and after those ages, "expected deaths" came out at 3 and actual deaths at 5. Counting in the private cases also, it appeared that 15 actually died, whilst 8 could be counted as "expected deaths," so that the mortality of exophthalmic goitre was apparently twice that of people in general. It must be remembered also that all were either ill enough to go to the hospital or seek a second opinion. The figures did not include those dying in the hospital, who were, of course, unsuitable for operative treatment. On 18 patients who died in hospital and who were not operated upon, 11 had fatal diarrhœa and vomiting, 6 became delirious, and 1 comatose. Two had melancholia and 1 mania. In 1 case mitral disease was present, and in 1 endocarditis and pericarditis were present. Two had rheumatic fever. Two had pneumonia and 1 bronchopneumonia. One died from diabetic coma. Of the 7 private patients who died (apart from operation), 1 succumbed to phthisis, 1 to pleural effusion, 1 to heart disease, 1 to alcoholism, 1 to diarrhœa, and 2 to diabetes. Forty cases could be traced of patients who had not been operated upon, and did not die in the hospital; 26 did very well, 12 did moderately well or were better, and 2 were no better. Of 47 seen in private practice who neither died nor were operated upon, 35 did well, 9 moderately well, and 3 not well. In all, 87 cases came under this category, of whom 61 did very well, 21 moderately well, and 5 were no better. Of 11 who had been operated upon, 4 died as the result. Only one reported herself as feeling perfectly well; the others were much better, but not cured. Actual deaths among sufferers from exophthalmic goitre, ill enough to go into hospital or seek a second opinion, were 15 as against 8 expected among healthy females, although these patients afflicted with exopthalmic goitre included severe and very severe cases. As, on the other hand, cases selected for operation were usually mild, and a few died as an immediate result, it hardly seemed likely that operations on the thyroid could diminish greatly the deaths that might, if the patients were not operated upon, be expected among such sufferers from exophthalmic goitre as would be selected for operation. If the operation became at all common it would be because it got the patients well more quickly and more perfectly.

The discussion was then adjourned.

MEDICAL SOCIETY OF LONDON.

Intrinsic Cancer of the Larynx Treated by Laryngo-fissure.—Aching Throat.

A MEETING of this society was held on Feb. 12th, Dr. J. MITCHELL BRUCE, the President, being in the chair.

Before proceeding to the business of the meeting the PRESIDENT referred in sympathetic terms to the great loss that the Society had sustained in the last few days in the death of their greatly respected Fellows, the late Lord Lister and Sir William Allchin. A vote of condolence with their nearest relatives was passed by the Fellows standing.

Dr. STCLAIR THOMSON read a paper on Intrinsic Cancer of the Larynx treated by Laryngo-fissure, with 80 per cent. of lasting cures. He considered that cases of cancer of the larynx might be divided into two groups—intrinsic and extrinsic. This classification was of the greatest importance, for whilst extrinsic cancer was, according to Butlin, "a dire disease," it was quite otherwise with intrinsic cancer: there was probably no other region of the body where operation for cancer could show anything like the satisfactory results that could be obtained when the disease occurred in the interior of the larynx and was removed by laryngo-fissure. There were two principal reasons why statistics and reports were not more frequently forthcoming: (1) Many cases did not consult a laryngologist for a persistent hoarseness until too advanced for a successful operation, and (2) cancer of the larynx was not a common disease. Ten cases had been operated on between the years 1900 and 1910, a period of ten years. The duration of the cure in each case from the date of operation to February, 1912, had been as follows: 1 case, 7½ years; 1 case, 4 years 4 months; 1 case, 3 years; 1 case, 2 years 2 months since laryngectomy; 1 case, 2 years 1 month; 2 cases, 1 year 3 months. One case died from other causes 15 months after operation, 1 case died from cancer of the tongue on the opposite side three years after operation and without local recurrence, and 1 case died from local recurrence. The conclusions to be drawn from this record could be stated fairly briefly. All the patients were male. Their ages varied between 43 and 68. Five, or 50 per cent., were under 50, 4 were between 50 and 60, and 1 was nearly 70. In no case did thyrotomy reveal any error of diagnosis. The death-rate from the operation was *nil*. Only 1 case was dead from local recurrence. A second case died from separate development of cancer in another part of the body. A third patient was dead from another cause. Laryngo-fissure alone had yielded a lasting cure in 80 per cent. of cases. Laryngo-fissure, supplemented by excision of the larynx in a case of local recurrence, had preserved 90 per cent. of the patients. In the only two cases in which there was local recurrence the disease reappeared within the year following the operation of laryngo-fissure. This fully confirmed Sir Felix Semon's conclusion that there was little or no anxiety as to return of intrinsic cancer if the larynx remained free for 12 months. Some points of diagnosis—mobility of the affected cord and preliminary microscopic examination of removed portion—were then referred to, and the paper concluded with some consideration of anæsthesia and surgical technique.

Sir FELIX SEMON said he was glad that Dr. StClair Thomson's experience bore out the points which he (Sir Felix Semon) had emphasised in his paper five years ago. At one time the operation of laryngo-fissure had fallen into disrepute and for ten years no one attempted it, but it was the late Sir Henry Butlin who had restored it to its proper position. He thought that there was some improvement in recent years in the stage at which patients were sent by practitioners, but there was still room for further improvement, not only in England, but all the world over. After long-continued hoarseness patients should be sent for efficient examination by a specialist. He thought that many of the so-called recurrences were not really recurrences, speaking scientifically, because they did not occur either at the site of the original growth or in lymphatic connexion with it. Occasionally, too, the second growth was of quite a different kind. He still held to the statement that if recurrence did not occur within one year the patient would probably remain free. He emphasised the importance of occlusion of the lower air-passages during the operation.

Mr. P. R. W. DE SANTI said that he had operated upon eight cases for intrinsic cancer of the larynx within 12 years. Seven were men. One was wrongly diagnosed as sarcoma, and proved to be a benign papillary growth. One had recurred 14 months later in the glands. The longest period of immunity after the operation was 11 years. As the result of experimental injections to show the distribution of the lymphatics, he still held that the division into extrinsic and intrinsic growths was the most satisfactory. All the seven cases recovered.

Mr. E. B. WAGGETT said that epithelioma of the larynx was a disease of extremely low malignancy, and consequently was especially suitable for operative treatment—facts which were imperfectly recognised by the profession generally. In order to obtain such cases early enough, it should be insisted upon that all practitioners should be able to see the inside of a larynx during life before they passed their final examinations.

Mr. HERBERT TILLEY recorded a case in which the operation had been successful for 13 years. Then the patient died, and a hard button-like epithelioma was found post mortem. Another case illustrated the slight degree of malignancy, since symptoms were present for five years before the diagnosis was confirmed, and operative treatment was deemed necessary. He did not think that bleeding after the operation was due to adrenalin having been used, but rather to the degenerate state of the arteries in elderly patients.

Dr. G. WILLIAM HILL said that, in his opinion, primary extrinsic cancer of the larynx did not exist. He thought that the cases described that evening were not so much characteristic of intrinsic cancer of the larynx as of cancer of a small area of the larynx, "the vocal cord area." These were peculiarly operable. What he had called "party-wall" cancer was not so suitable for laryngo-fissure, as it soon spread and became extrinsic.

Dr. W. H. KELSON read a paper on "Aching Throat." He pointed out that although not serious to life aching throat was important, because very common, very depressing, and very persistent. The patients were mostly middle-aged, and might belong to either sex. They might show the various signs of chronic pharyngitis and other local pathological conditions, but these might be entirely absent and the throat appear normal. Anæmia, gout, or rheumatism might be present, but the treatment of these alone seldom cured the aching. Most commonly the patient suffered from flatulent dyspepsia with constipation. The nerve-supply was exceedingly rich and varied, but, on the other hand, the sense of locality in the pharynx was very vague, consequently pain was often referred to parts in this region other than those actually stimulated. Neurotic conditions and over-use of the voice would not explain the majority of cases of "aching throat." A number of cases were then referred to, including two in which the cause had been salivary calculus. Since dyspepsia was by far the most common associate of aching throat, this must especially be treated, the assistance of a dentist was very often necessary, and the question of diet must be carefully gone into. Cleansing washes and gargles might be used for the throat and nose, but operative treatment had better be avoided in the first instance. The aching might be due to toxins, or perhaps be a referred pain from the stomach.

OPHTHALMOLOGICAL SOCIETY.

Exhibition of Cases.

A CLINICAL meeting of this society was held on Feb. 8th, Mr. J. B. LAWFORD, the President, being in the chair.

Mr. ROBERT W. DOYNE showed a case of Guttate Iritis. He said that he had never seen a case in a man. The guttæ were independent, in position, of the inflammatory points. The guttæ within a few days might have completely changed their position. In this patient a week ago there were four well-marked guttæ, but now there was only one. It seemed to be an exudation between the layers of epithelium where it was reflected; usually the subjects of the condition were gouty.—The PRESIDENT reminded the members of the cases shown by Mr. Doyne two years ago, and they seemed to have occurred only in cases of chronic iritis. If the condition happened in acute iritis it might be missed in the general haze.

Mr. CHARLES WRAY showed three cases of Frontal Sinus Disease, with pathological specimens; also a severe case of Ingrowing Lashes treated by the electro-cautery. He said that although Siegler advocated that for entropion the cautery should be at a white heat, his own experience was that it was better at a dull red heat, and he preferred the thermo-cautery.

Mr. WRAY also showed a Cyclo-photometer and described his method of testing.—The matter was discussed by Mr. C. A. WORTH, who referred to a book he published ten years ago on the subject.

Mr. G. COATS exhibited a case of Unilateral Proliferation of the Uveal Pigment, and Mr. E. TREACHER COLLINS one of Unilateral Melanosis of the Uvea and Sclera, with elevations on the affected eye. These were discussed together. Mr. Coats said there was evidence that the spot was there shortly after birth, and it had increased considerably in the last year. There was increased pigmentation of iris, fundus, and sclera. The point of most interest was the presence of elevations on the surface of the iris. Twenty-six cases of the kind had been recorded, and of those no fewer than seven developed sarcomata in the eye late in life. The commonest age for it to occur was between 50 and 60, and the age of the youngest case recorded was 34. Mr. Treacher Collins said he had his case under observation and care, backwards and forwards, for ten years. Not every case of melanosis showed elevations on the iris. Some years ago he showed, at the society, sections at the seat of melanosis, apparently dating from birth, in a man aged 60. He thought it was melanotic sarcoma of the ciliary body. He recently re-examined that section and found it remarkably free from elevations.—Mr. F. HEWKLEY raised the question whether it was the rule for the irides to be a light grey colour at birth.

Mr. LESLIE J. PATON showed a case of Holes in the Macula, which he considered differed from ordinary cases of the kind and from the 15 cases collected in Mr. F. M. Ogilvie's paper in the fact that the hole had a bluish-white background. There was no history of injury in the case, yet there was some evidence that it was a recent occurrence. There had evidently been considerable retinal disturbance all round the macular region. Apart from the holes, the general appearance was like that of albuminuric retinitis, but there was no trace of albumin in the urine and no other organic disease.

Mr. R. A. GREEVES showed again a patient with Recurrent Unpigmented Tumour of the Sclera, the case having been brought forward originally in October last. Removal was done, and later there seemed to be a recurrence, but the scar tissue which began to form seemed to strangle the tumour, and it had now disappeared. The first tumour was pronounced to be a very cellular hæmangioma.

Mr. J. F. CUNNINGHAM showed two cases: (1) Cholesterine Crystals in the Anterior Chamber; (2) Retinal Hæmorrhage and Exudation in a young subject. The second case he regarded as one of vascular disease.—The PRESIDENT, discussing Mr. Cunningham's second case, said he saw the lad in hospital and no condition had been found which was likely to be causally related to the eye condition; nothing, for instance, in the blood-cell count, or the coagulation time, or the presence of any bacterial condition. The possibility of lead-poisoning had also been excluded.—Mr. DOYNE considered that the case belonged to the class which Mr. H. Eales

had worked at, and which he called spontaneous hæmorrhages, but which had not had much light thrown on them. He tried to find out something about the condition years ago, and was convinced that the veins, not the arteries, were responsible for the hæmorrhage. The cases seemed to be limited to men, but not to young men, as Mr. Eales thought. The whole eyeball might appear to be suddenly filled with blood. The cases which he had seen recovered, sometimes with very good vision, leaving some silvery stains in the retina, and sometimes some membrane in the vitreous. In one case he found that the blood tension was very low. The von Pirquet test was positive.—Dr. T. HARRISON BUTLER said Professor Axenfeldt had proved several of these diseases to be due to alterations in the retinal vessels, and he pointed out that nearly all the cases had a tubercular basis.—Mr. PATON did not agree that these cases were analogous to cases of intravitreous hæmorrhage. One case he saw had some cranial nerve palsy.—Dr. E. FARQUHAR BUZZARD said he knew the case to which Mr. Paton alluded. It was not a case of true Bell's palsy, because only certain fibres of the facial nerve were affected. He thought it might have been due to a local hæmorrhage in the facial nucleus or the facial nerve. One could easily imagine, following on Mr. Doyne's suggestion, that it might be caused by a small tubercle in the pons.—Mr. CYRIL H. WALKER referred to the case of a man, aged 21, who was healthy, but the sight of one eye was bad. He had many streaky-looking hæmorrhages in the nerve fibre layer—there were ten fairly large ones, the largest a quarter the size of the disc, and there were 20 smaller ones. In three weeks the sight improved a great deal. There was no macular star. Two months later the patient had a very large intra-ocular hæmorrhage which blotted out everything. That remained opaque until two months later, when it began to get translucent. The treatment was mainly rest, and the patient was also given some mercury.—Mr. D. LEIGHTON DAVIES related the case of a male clerk, aged 19, who came complaining of severe headaches, and that a few days previously he was blind in his left eye. In the fundus striate hæmorrhages were found over the retina, and dilatation of the vein with white exudation in the macular region. It looked like a case of albuminuric retinitis, but a physician found the urine normal.—Mr. W. H. H. JESSOP considered such cases were somewhat allied to Raynaud's disease or even hæmophilia; the subjects of it, when struck, rapidly became bruised. There seemed to be some defect in the coat of the arteries leading rapidly to transudation.—The discussion was continued by Mr. RAYNER BATTEN and the PRESIDENT.

Mr. A. H. P. DAWNAY showed a case of Persistence of Anterior Portion of Hyaloid Artery.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases.—Tuberculous Peritonitis in Adults.—Ortho-Roentgenography of the Heart and Aorta.

A MEETING of this society was held on Feb. 7th, Mr. J. M. COTTERILL, the President, being in the chair.

Mr. CHARLES W. CATHCART showed: 1. A female patient after Removal of a Calculus from low down in the ureter. The woman had been subject to frequent attacks of severe renal colic during the last two years. A renal calculus had been removed from her in another hospital some months previously. Her attacks, however, continued as before and she was sent to Mr. Cathcart. An X ray photograph showed a stone lying low down in the left ureter. This ureter was exposed by an extra-peritoneal operation, the ureter opened above the brim of the pelvis, and the stone removed with a loop of copper wire mounted on a handle. 2. A patient after Wiring of the Humerus; Musculo-spiral Paralysis following. Paralysis of motion was observed shortly after the accident, but sensation remained nearly complete. At the operation the musculo-spiral nerve was found to be stretched over the upper fragment, which was displaced backwards and was involved in callus. The bones were replaced and wired; the nerve was freed, and recovery was steadily advancing.

Dr. G. L. GULLAND showed: 1. A case of Myxœdema occurring in a woman aged 44. She had complained of swelling of the face, neck, and eyes during the past three years with weakness, loss of appetite, and breathlessness. Her temperature was subnormal, the face swollen, and the features coarse. Her skin all over was dry and thick, not pitting on pressure. The right lobe of the thyroid was enlarged; nothing was to be noted in the blood or urine. Mitral stenosis was present, and the case was as yet untreated. 2. A case of Tabes Dorsalis. The patient was aged 83. There was a history of spinal disease, dating 17 years, and treated by stretching. There was no history of syphilis; Argyll Robertson pupil and Romberg's sign were present, also general muscular weakness with absence of the deep reflexes; incoördination was marked with indefinite impairment of common sensations. Lymphocytosis was present in the cerebro-spinal fluid, and Wassermann's reaction was negative. Partial paresis of both third nerves was present with hemiatrophy of the tongue.

Professor F. M. CAIRD showed a case of Entero-vesical Fistula in a man aged 51. He discussed the causes, the advantages of cystoscopy, and laparotomy. He described the separation of the carcinoma of the sigmoid from the base of the bladder, and how enterectomy had to be performed for removal of the carcinoma; how the bladder wound was closed, end-to-end union of the intestine was accomplished, and finally appendicostomy was performed.

Professor CAIRD read a paper on the Treatment of Tuberculous Peritonitis in Adults by Operation. In every instance definite evidence of the lesion was ascertained, and only those cases were considered in which peritoneal invasion was the chief manifestation of the disease. Consequently, early examples of tuberculous appendicitis, tuberculous stricture of the intestine, and tabes mesenterica were excluded. On the other hand, tuberculous disease of the Fallopian tubes and ovaries, with marked extension to the peritoneum, and also cases of general adhesive tuberculous peritonitis with infiltration of the serosa and other coats of the bowel were included. For convenience a common classification was adopted, consisting of a series of types running into each other, but which might be placed under the headings of: (1) Cases with fluid exudate predominating; (2) the same plus adhesions and matting, with the exudate sometimes encysted; (3) dry forms with or without adhesions; (4) dry adhesive forms in which the peritoneal cavity was practically obliterated, and in which there might also be an extension to the intestinal wall from the serous surface inwards. The general symptoms presented by the disease were fairly uniform and well recognised. They were best marked in the exudative varieties. The patient complained of a progressive, sometimes slightly intermitting, swelling of the abdomen. There were abdominal discomfort and pain, loss of strength and weight, and constipation was usually present. As the distension increased nausea and vomiting arose, the urine became scanty, and there was frequency of micturition. If there were in addition marked adhesions and infiltrations of the omentum, localised resistant areas and tenderness might be discovered and the general abdominal doughy feeling so often present was familiar. The dry varieties were still more likely to be associated with localised tenderness and resistance; diarrhœa suggested implications and kinking of the intestine. As a rule there was but little rise in the temperature; the pulse-rate was apt to increase with the abdominal distension as also the respiration. The antecedent history was helpful in confirming a diagnosis, and the patient might have enlarged cervical and axillary glands, a tuberculous apex, or may retain the memory of an old pleurisy. Moreover, similar histories of tubercle occurring in the immediate relatives might be elicited. Definite evidence on this point was only positive in 11 out of 31 cases. It was a curious fact that trauma had not been recognised as a factor in causing tuberculous peritonitis, and only two of the cases stated that they had a previous abdominal strain. In two women the condition followed closely on their last confinement. It was interesting to note that in three cases, after excellent recoveries from operations for ruptured gastric ulcer, for duodenal ulcer, and for gastic carcinoma, the three patients returned with tuberculous peritonitis. In no case during the previous laparotomies had there been any indication of tubercle observed. As regards sex there were 13 males and 18 females. The males were from 17 to 60 years of age, averaging 32; the females from 13 to 51, averaging 22 years. In but few cases did the diagnosis present any difficulty, although it must be admitted that of the older patients some were subjected to operations with a possible diagnosis of

malignant peritonitis, and it is still more instructive that the conditions found on incision so closely simulated that disease in every detail that only the microscopic examination of removed portions of diseased peritoneum and tissue removed, as also the after-history, demonstrated the true nature of the pathological process. Most of the patients were referred to the surgical ward after having undergone treatment by the physicians on the medical side. The surgical treatment consisted in an incision midway between the umbilicus and the symphysis pubis, and occasionally in the linea semilunaris or ileo-cæcal region, according as circumstances seemed to demand. On opening the peritoneal cavity an attempt was made to discover and remove any abdominal focus. This was seldom successful, since no prolonged search seemed advisable, and only on two occasions was it thought right to remove tuberculous tubes and ovaries. In two others masses of infiltrated omentum were excised. In such cases, and also where the exudate was purulent, a drainage-tube was employed for a short period, and the peritoneum was gently douched with warm sterile salt water. In the majority of cases, after freeing adhesions and evacuating the fluid, the abdomen was at once closed. The dry and adhesive type of tubercle required great care in manipulation, more especially in dividing the thickened peritoneum, which was often almost inseparably blended with the subjacent coil of bowel. In one patient, despite special vigilance, the bladder was accidentally opened; it lay 1½ inches above the pubes and was fused with the parietal peritoneum. In two other cases the separation of adhesions gave rise to laceration of infiltrated small intestine, and a double enterectomy became necessary. Two cases of fæcal fistulas followed simple exploration in purulent cases; one healed, the other ultimately succumbed. The immediate results of operation were that of 31 cases 27 recovered. Of 13 males, 2 died; and of 18 females, 1 died after operation. Of the males, one was an emaciated youth, aged 18, who had suffered for 18 months with abdominal swelling, pain, tenderness, vomiting, and diarrhœa. He had a large hour-glass abscess of the abdomen and pouch of Douglas, which also contained gas and fæces. After drainage and enterectomies he at length sank, four months later, from general tuberculosis. The other one died within 16 days from a general tuberculous peritonitis, with marked additional tubercle of the lungs, liver, and spleen. The female, who was aged 17, sank 19 days after operation from general tuberculous lymphadenitis and tuberculous peritonitis. All of the dry varieties healed, although such cases are not regarded so favourably from a surgical standpoint as those which abound in fluid. All of the patients with two exceptions reaped direct benefit from operation. Two showed no improvement and eventually died. Whatever temporary good may follow operation it is mainly by the ultimate gain that the value of surgical intervention must be gauged. It is unfortunately no easy matter to supply this. Not only is it difficult to trace cases, but should the patient have died since leaving hospital definite information as to the cause of death is rarely forthcoming. Of the 27 recoveries 10 cannot be traced. Nine died at varying periods. Eight are known to be alive and well: one 9 years, four 5 years, one 4 years, one 3 years, and one 2 years after operation. If such results are not brilliant they at least justify surgical treatment. The general condition of patients suffering from tuberculous peritonitis is always bad; their nutrition, their resistive powers are very low. None of the cases were selected; they were all in poor condition and, as already stated, the greater number had ceased to respond to the aid of the physician, and it is only after a fair trial of medical measures that the question of operation should be entertained. The curative effect of laparotomy has been ascribed to various factors—the removal of a passive injurious effusion, thus relieving the general tension, the favouring influence of the succeeding hyperæmia of the peritoneum which ensues, and the preparing of active antibacterial fluid all play their part. Bumm has found on following a first laparotomy by a second that the tubercles on the second occasion were invaded by lymphoid cells and deprived of their bacilli. Only one of the series had been treated with tuberculin as far as was known. It would probably be a wise thing to make use of this adjuvant both before and after operation in all such cases.—A long and animated discussion took place at the conclusion of the paper.

Dr. W. HOPE FOWLER and Dr. W. T. RITCHIE read a paper on Ortho-Roentgenography of the Heart and Aorta (with lantern demonstration). The technique of the method having been described, the normal cardiac outline was discussed. There are two curves of the right side, and either three or four on the left. The variations of these curves in health, their form and pulsations, were indicated. The respiratory movements of the heart are more extensive than the pulsatile, and the form of the cardiac silhouette differs according to the phase of respiration at which the record is taken. The records were measured according to Groedel's method, measurements being also taken from the patient's right fist as standards, according to Levy-Dorn and Möller, for the size of the normal heart. Pathological conditions affecting the heart are more readily characterised by alteration of the cardiac silhouette than by variation in size alone. In well-marked cases of mitral incompetence the two lower curves on the left side are prominent. In mitral stenosis, with the auricular musculature contracting in a coördinate manner, the heart is rather vertical, the outline curves are sharply demarcated from each other, the left auricular and pulmonary curves are especially prominent, while that of the left ventricle may be diminished. Mitral stenosis, with auricular fibrillation, is characterised by a large, globular heart, with bulging of the pulmonary and both auricular curves. In aortic incompetence the "recumbent egg-form" is not constant, although the curve of the left ventricle is enlarged. Combined aortic and mitral incompetence presents a larger and more dilated heart. Illustrations were also shown of orthodiagraphic outlines from cases of mediastino-pericarditis, patent ventricular septum, patent ductus arteriosus, chronic interstitial nephritis, and aortic aneurysms. The orthodiagraphic and percussion outlines of various hearts were compared with one another, and it was shown that the left border of the heart and the upper limit of the liver, as ascertained by firm percussion, frequently lie too far to the left and too high respectively, while the right percussion border may be too near the mesial line. Owing to the oblique position of the heart within the thorax the basal portions of the heart offer special difficulty to accurate delimitation by means of percussion. The position, size, and form of the heart cannot be delimited so accurately by percussion as by the orthodiagraph.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Feb. 2nd, Mr. H. Littlewood, the President, being in the chair.—Mr. J. A. Coupland read a paper entitled "A Year's Experience of Salvarsan." He referred to 20 cases treated in the primary and secondary stages of the disorder. The treatment in the earlier cases had been by intramuscular injections; latterly by two intravenous injections of 0·5 or 0·6 gramme. The average period of observation had been six months. In two cases recurrence of secondary symptoms had followed at two and seven months' intervals after intramuscular injections. In one primary case recurrence had followed one month after 0·6 gramme intravenous injection. In all these cases further intravenous injections had produced a rapid disappearance of symptoms. In one case recurrence was present after two 0·6 doses, given intravenously. In two cases, in spite of a negative Wassermann, enlargements of lymphatics were still present, and he did not regard the cases as cured. In two cases the reaction had been alarming; in one this was immediate and to be attributed entirely to faulty technique. The solution injected was not clear, but showed a flocculent precipitate. This was given at a time when the giving of an emulsion intravenously was recommended, a method which was now entirely abandoned. In the second case two intravenous injections—0 6 gramme in a clear, slightly alkaline solution—had been given at a fortnight's interval to a patient who had contracted the disorder seven years previously. The reaction after the first dose had been very slight. Three days after the second the patient became dazed; on the fourth day he became comatose and had epileptiform convulsions and remained in this condition for two days. A complete recovery had followed. Mr. Coupland, after commenting on the similarity of this case to others recently reported, was inclined to attribute this alarming train of symptoms to the short interval between the injections and to the fact that the patient had not been confined to bed after the second injection. No symptoms of cerebral syphilis had been observed before the injections; the patient had lived a healthy life, but was in a very restless and worried condition before treatment. Half of

the cases treated had, however, been treated with a similar dosage without any bad symptoms, and in only two had the second reaction been slightly more pronounced than the first. He was inclined to advise a period of two months between the injections, and the maintenance of at least three days in bed both before and after every injection. A review of the fatal cases already recorded showed that faulty technique and the inclusion of cases of gross cerebral, arterial, or renal lesions were responsible for the great bulk of the fatalities. Further knowledge of the rate of excretion of the drug and the factors which disturbed it was needed before the degree of danger attached to this treatment were definitely determined. He laid stress on the fact that the most satisfactory results had so far followed the treatment of the primary stage of the disorder before a positive Wassermann had appeared; the diagnosis should first be corroborated by the finding of the specific organism. The importance of following up the cases so treated and the necessity of accumulating evidence of the permanent value of the treatment were referred to. Mr. Coupland thought that the obliteration of the secondary stage was already more rapid, more easily obtained, and more complete than could be obtained by mercurial treatment. The resulting improvement of the patients' health, as evidenced by absence of anæmia, by increase in weight, and by their frequently expressed sense of well-being, contrasted favourably with the conditions noted under the older treatment of the same class of hospital patient. The more rapid and complete obliteration of the secondary stage was regarded as of distinct value to the community, as it must surely diminish the risk of accidental infection of the family and associates of the syphilitic. The question of a subsequent course of mercury was at present an open one; it would certainly have to be adopted where a positive Wassermann persisted after repeated injections of "606." Its routine adoption could only stultify the experience which everyone was anxious to obtain as to the ultimate value of the remedy.—Cases and specimens were shown by Mr. J. F. Dobson, Dr. G. W. Watson, Dr. Alex. Sharp, Dr. T. Churton, Dr. J. B. Hellier, Mr. A. L. Whitehead, Dr. R. A. Veale, Mr. L. R. Braithwaite, Dr. C. Oldfield, Mr. W. Gough, Mr. H. Littlewood, Dr. T. Wardrop Griffith, and Dr. W. H. Maxwell Telling.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—A meeting of this society was held on Feb. 9th, Professor A. Bostock Hill, the President, occupying the chair.—Dr. G. A. Auden, in a paper on Open-air Schools, said that during the last decade popular imagination had been aroused to a recognition of the value of fresh air in the treatment of tuberculosis, but just as the value of sanatorium treatment for phthisis was very largely the education or effect which its popularity had upon the community, so, too, would this be the case with open-air schools. Valuable as such institutions would be to the individual child who was fortunate to obtain admission, they would fail of their chief opportunity if they did not lead to the application of similar open-air principles to the organisation of ordinary elementary schools. Open-air schools of the Charlottenburg type had now been established by several local education authorities in England, notably in Barnsley, Halifax, London, Norwich, Sheffield, Bradford, and Birmingham. In the two last-named towns buildings had been specially erected; in the others existing buildings had been adapted. After describing in some detail the Birmingham school, which was the gift of Mr. and Mrs. Barrow Cadbury, Dr. Auden stated that during the four last months of last year when it was occupied 89 children were in regular attendance. Of these, 35 per cent. showed great improvement, 50 per cent. some improvement, and 15 per cent. remained stationary. Investigations had shown that about 10 per cent. represented the number of school children whose malnutrition and depressed vitality called urgently for education on open-air lines. The same principles which underlay the open-air school organisation could be applied without difficulty to the school curriculum in the most crowded areas of a manufacturing city. One of the means which lay readiest to hand was the provision of playground classes. Finally, Dr. Auden insisted that the management of an open-air school should remain a matter entirely under the jurisdiction of the school medical officer.—Dr. E. W. Hope considered that all developments such as open-air schools must have an enormous influence in improving the condition of all schools, for it must be realised that even good schools are very far behind what is considered necessary. He approved of playground and roof classes.—Dr. W. Butler urged that if an open-air school was of such value to children below normal to whom exposure might be considered to be serious, how much more valuable should they be to the normal child. He thought that existing schools might be simplified and that permanent structures were not necessary, and advocated the closing of the sides of a school building by means of canvas stretched on wood, so that any or every side might be more or less completely opened.—Dr. C. Sanders deplored the apathy and want of interest among teachers who were afraid of draughts and had not been educated on modern lines.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.—An meeting of this society was held in the Royal Victoria Infirmary, Newcastle-on-Tyne, on Feb. 8th, Dr. A. Angus Martin being in the chair. The evening was devoted to the demonstration and discussion of medical and surgical cases as follows.—Dr. Martin showed a woman in whom he had removed the uterus for Chorion Epithelioma, and in whom there was evidence of secondary lung involvement, bloody expectoration, &c. She was in excellent health, some months having elapsed since hysterectomy. The specimen was also shown.—Dr. T. Beattie exhibited a boy, aged 18, the subject of Acute Chorea, accompanied by maniacal symptoms. He enlarged on the urgency of inducing sleep by heroic doses of hypnotics. The boy had mitral stenosis with regurgitation.—Mr. A. Parkin showed a case of Cervical Rib, on either side the rib pressing on the lower trunk of the brachial plexus and producing nervous symptoms, neuralgia, paræsthesiæ, &c. An operation had been performed on both sides, with cure on the right and some relief on the left side.—Mr. Parkin also brought forward a case of Irregular First Rib, its anterior end being deficient, and not coming up to its sternal articulation, but appearing to be attached to the upper surface of the second rib. The inner end of the clavicle was also malformed and less prominent than its fellow. The deformity was undoubtedly a rare one.—Mr. H. B. Angus showed a man from whom he had removed a large Sarcoma of the Thigh. The seat of disease was being treated with Coley's fluid, the dose having been increased to 10 minims. The patient was in good condition.—Dr. R. A. Bolam showed a case of Carcinoma of the Male Breast, which was receiving X ray treatment, and which exhibited a very marked degree of fibrosis and contraction. He also showed cases of Nævus Linearis and Pemphigus.—Mr. W. G. Richardson demonstrated a case after operation for Ruptured Gastric Ulcer, which was followed by pleural infection and empyema. It was of interest that on admission, four hours after rupture, pleural implication was suspected and constantly watched for.—Mr. J. Clay exhibited a case of apparent Spontaneous Cure of Epithelioma of the Penis in a patient with undoubted syphilis. The microscopic report was only "suggested" epithelioma, and thus the disappearance of the lesion under iodide and mercury might be accounted for by its being a gumma of the penis.—Dr. Hamilton Drummond showed a case of Traumatic Cerebral Hernia following Compound Fracture in the Right Temporal Region. Spontaneous cure was looked for.—Dr. Horsley Drummond showed a case of Cachectic Infantilism, the patient being 22 years old, and 4 feet 6 inches in height. He had markedly enlarged liver and spleen and considerable dyspnœa. A positive Wassermann reaction had been obtained, while no evidence of pancreatic disease could be demonstrated. It was suggested to be of pituitary origin.

DEVON AND EXETER MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Feb. 9th, Dr. R. V. Solly, the President, being in the chair.—Dr. F. W. Price (London) read a paper on Recent Advances in Heart Disease. The paper was illustrated by the polygraph. He contrasted the respective rates of advance of medicine and surgery. He then discussed cardiac irregularities in patients with no evidence of valvular disease, and the diverse results of treating identical lesions with digitalis. He reminded his hearers that irregularity might be the only detectible physical sign of myocardial degeneration. He maintained that the variability of action of digitalis was due neither to caprice nor to diversity of the preparations of the drug. The enormous advance in knowledge of cardiac disorders was largely related to the graphic methods rendered possible by the advent of the clinical polygraph. Dr. Peric

then demonstrated the Mackenzie polygraph. He laid especial stress on the importance of studying the *a.-c.* interval with a view to accurate comprehension of the conductivity possessed by any given heart. By means of the polygraph irregularity, from being a vague and complex unity, had now become a classified disease. Dr. Price then passed on to the problem of digitalis, and stated that those cases of cardiac failure which showed markedly good results were cases of auricular fibrillation. In conclusion, he pointed out the harm which would accrue from the exhibition of digitalis in cases of depressed cardiac conductivity, and hence the importance of the investigations now made possible by the graphic methods.—The President, after thanking Dr. Price on behalf of the society for his interesting and valuable paper, discussed the question of cardio-sclerosis without valvular lesion. He also asked Dr. Price what value he attached to the use of strychnine in cardiac disease and what treatment, if any, was of value in cases of heart-block.—Dr. A. E. Carver mentioned his frequent observation of a dropped beat form of irregularity in senile cases exemplifying sinus irregularity. He had found the polygraph invaluable both at the beginning and end of treatment as a gauge of progress. He endorsed the value of digitalis in massive doses where irregularity was related to auricular fibrillation.—Dr. Price, in reply, said that the action of strychnine, so far as was known, appeared to be *viâ* the blood-pressure apparatus. No drug had yet been found capable of stimulating the ventricle in heart-block.

WIGAN MEDICAL SOCIETY.—A meeting of this society was held on Feb. 8th, Mr. F. L. Angior, the President, being in the chair.—Dr. R. Prosser White showed: 1. Acrodermia Neuritica. The patient sustained an injury to the right hand and forearm four years ago. At the present time there was progressive atrophy of all the constituents of the forearm and hand, bone, muscle, and skin. The latter was exceedingly thin, ulcerated in places, and acutely sensitive. Also X ray photograph. 2. Dermatitis Artifacta. A girl, about 16 years old, whose only symptom was the appearance about once a week of one or more bullæ on left arm and shoulder. These arose in the night and were first seen when she got up in the morning. She was admitted as an in-patient and treated by rest, isolation, suggestion, and feeding, and no fresh bullæ had appeared. 3. Molluscum Fibrosum. A woman with warty-looking fibroid growths in the left axilla. Also section of one under the microscope.—Dr. Harry Holmes showed: 1. A case of Tumour of the Pituitary Gland. A man, aged 27, height about 4 feet, at present nearly blind, and suffering from enormous protrusion of both eyeballs. Hair scanty and thin. Reproductive organs elementary. He had fits of some kind at the commencement of his illness, and then bi-temporal hemianopsia. Dr. Holmes referred to the two types of case due to pituitary tumour. The man had been seen by several surgeons, but operation had not been advised. 2. A case of Xerosis of the Conjunctivæ. The right cornea was now quite opaque, and the left was rapidly following. This condition he considered was due to some general systemic disease, such as congenital syphilis. The case has been under a variety of forms of treatment—antisyphilitic, thyroid, tubercular, &c.—but steadily retrogresses.

UNIVERSITY COLLEGE, DUBLIN, MEDICAL SOCIETY.—A meeting of this society was held in the College on Feb. 8th, Mr. J. S. McArdle being in the chair.—Professor E. J. McWeeney read a paper on Recent Views as to the Nature and Causation of Cancer. He outlined the various theories generally held, and emphasised the importance of the "irritation theory," but said that in cases where irritation gave rise to malignant disease they had to suppose another factor in the case—viz, the presence of a certain abnormal type of cell, the exact characteristics of which were still unknown. He outlined the work done, and still being done, in England, Germany, and other countries, on the inheritance of malignant disease in mice, and showed lantern slides of tables summarising the results. He also referred to the interesting results obtained in the endeavour to produce immunity from malignant disease in mice by the injection of pieces of embryonic mouse tissue. In spite of these results in mice the lecturer was of opinion that they were by no means as applicable to man as might be supposed, and suggested that the most fruitful line of work would be that of Wassermann, who has been trying to find, already with some measure of success, a synthetical drug capable of picking out the cancer cells and destroying them.[1]—The subsequent discussion was taken up by Dr. W. M. Crofton, Dr. J. H. P. Boyd Barrett, Mr. J. H. McAuley, Mr. H. S. Meade, and Dr. M. R. J. Hayes.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Feb. 4th, Mr. M. Parry Jones being in the chair.—Dr. A. C. Reid introduced a discussion on Trauma as a Factor in Some Diseases of the Nervous System. The subject of brain tumour and brain abscess was briefly referred to. More detailed reference was made to late traumatic apoplexy and meningitis, the work of Duret and Bollinger being specially mentioned.[2] Quincke's meningitis serosa was next brought under review: an interesting case published by Kurt Mendel and a recent case of acute acquired hydrocephalus following on shock being adduced as evidence of a possible traumatic origin for this rare condition. Myelitis and myelodelesis (Kienböck) were rapidly reviewed. Under the heading of "neuritis" special notice was taken of Erb's shoulder-arm paralysis. The paper concluded with remarks on traumatic epilepsy.—Mr. Parry Jones, Dr. F. H. Jacob, Mr. K. Black, Mr. A. R. Tweedie, Mr. A. M. Webber, and Dr. R Heelis continued the discussion.

Reviews and Notices of Books.

A Text-book of Physiological Chemistry. By OLOF HAMMARSTEN, Emeritus Professor of Medical and Physiological Chemistry in the University of Upsala. Authorised Translation from the Author's Enlarged and Revised Seventh German Edition. By JOHN A. MANDEL, Sc.D., Professor of Chemistry in the New York University and Bellevue Hospital Medical College. Sixth American edition. London: Chapman and Hall, Limited; New York: John Wiley and Sons. Pp. viii.–964. Price 17*s.* net.

THIS edition differs from the earlier ones by containing a new chapter on "Physical Chemistry in Biology," written by Professor S. G. Hedin, of Upsala. To give room for this new chapter, without changing the number of chapters in the earlier editions, the chapter on "The Animal Cell" has been dropped and its contents incorporated in other chapters. Otherwise the general plan remains unchanged, though necessarily with the great advances in physiological chemistry a considerable increase in the size of the book could not be prevented. The subjects successively dealt with after the introduction are: Physical chemistry in biology; proteins; carbohydrates; fats and phosphatids; blood; chyle, lymph, transudates and exudates; liver; digestion; connective tissues; muscles; brain and nerves; organs of generation; milk; urine; skin and its secretions; respiration and metabolism. The indexes of authors and the general index are both very full and complete.

It should be noted that there are no illustrations of any kind, either of spectra, apparatus, crystals, or curves, although smaller type is used to mark the less important matter. The result is that the text contains an enormous amount of information, the references to original papers when required being given at the foot of the page. A good, all-round grasp of organic chemistry is required to follow the work.

In the introductory chapter, which is admirably and concisely written, the reader is introduced straight away to the difficult and obscure problem of oxidation in animal tissues, and the newer results on oxidases, and such subjects as enzymes, "enzymotic" action, lipoids, and their suggested uses as a boundary layer in cells, autolysis and allied

[1] THE LANCET, Jan. 13th (p. 112) and 27th (p. 264), 1912.
[2] THE LANCET, Nov. 6th, 1909, pp. 1339 1360.

subjects, while the importance of ions is clearly emphasised. In the chapter on "Physical Chemistry" osmotic pressure, colloids, the importance of the ultra microscope, adsorption, gels, sols, catalysis, enzymes, their specific and their reversible actions, antigens and antibodies, ions and salt action, and allied subjects are treated in an interesting and practical manner.

A very full account is given of the proteins, amino-acids, polypeptides, and all the recent work which has been the outcome of the brilliant and stimulating researches of Emil Fischer. Perhaps on p. 86 "linkage" would be a better expression than "bindings" when the author is speaking of the possible combinations of amino-acids. The fact that no single protein reaction is in itself characteristic is emphasised, and, therefore, in testing for proteins one reaction is not sufficient. A number of precipitation and colour-tests must be employed. On p. 109 "Miesher" is obviously a misprint for Miescher; the name is correctly given elsewhere and in the index. Kühne's view on tryptic proteolysis is rightly set aside in the light of recent research, though, unfortunately, it still finds a place in some English text-books. The amino-acids are fully treated, as are also the purin bases, which in the last few years have attracted great attention both on the part of the chemist and the physician. The account of the carbohydrates and that of the fats are much on the lines of the last edition, but the phosphatids find their natural setting in this edition along with the fats.

Blood is concretely and fully dealt with. Perhaps on p. 243, for "effusion" of the mouth of the medicinal leech, the term "leech extract," as used in English text-books, would be more appropriate. In any case, "effusion" does not seem the correct word. The obscure subject of the origin of fibrinogen is critically discussed. In describing the oxygen absorption by hæmoglobin a curve showing this would be much more effective. We failed to find, either in the text or the index, a reference to the work of Soret on the absorption bands in the ultra-violet part of the spectrum, known in this country as the "bands of Soret," though Gamgee's work on this subject—which was subsequent to that of Soret—is referred to. The occurrence of hæmoglobin crystals in the stomach of the leech and the work of Brito and Stirling seem to be omitted. On p. 295, when speaking of the "tissue fibrinogen" of Wooldridge, instead of "digesting leucocytes with water," perhaps it would be better to state how Wooldridge employed the thymus gland.

Chyle, lymph, and allied subjects occupy pp. 327–359, while the liver is dealt with from pp. 360–425. In speaking of the occurrence of glycogen in the liver of molluscs, the mussel, but not the oyster, is mentioned. The account of digestion is elaborate, but concise. Here, again, curves to show rates of secretion would be valuable as well as helpful. As to absorption and the forces active in the intestine, "the question has not been answered." Consecutive chapters deal with connective tissue, muscles, brain and nerves, organs of generation, milk, and urine, and we find a singular mistake on p. 756 in connexion with the sulphur test for the bile salts in urine. It is attributed to Haycraft instead of Matthew Hay—a mistake that has been made before. The skin and lungs (pp. 789–821) are next considered, and then metabolism (pp. 822–880). A very guarded opinion is given on Chittenden's observations on diet, which will be found on p. 877.

The work is highly to be commended as a treasury of facts and as a critical, well-reasoned exposition of those facts in relation to the chemical activities and processes that occur in animals. We cordially commend it as a text-book and a book of reference.

Diseases of the Anus, Rectum, and Sigmoid, for the Use of Students and General Practitioners. By SAMUEL T. EARLE, M.D., Professor Emeritus of Diseases of the Rectum at the Baltimore Medical College; Surgeon in Charge of Rectal Diseases at St. Joseph's Hospital, the Hebrew Hospital, and the Hospital for Women. With 152 illustrations. Philadelphia: Lippincott Company. 1911. Pp. 476. Price 21*s.* net.

MANY medical men in practice find the knowledge of diseases of the rectum acquired when they were students inadequate for their daily work, and this book may afford them real assistance.

The anatomy and physiology of the rectum are sufficiently described to recall to the reader the essentials. The author considers that in the majority of rectal operations it will be found more satisfactory to use a general anæsthetic, unless its employment is specially contra-indicated. He is opposed to spinal anæsthesia, partly because of the deaths which have occurred under it, and partly on account of some of the sequelæ. A long chapter is devoted to the consideration of the treatment of constipation. The general methods of treatment—such as diet, exercise, and massage—are well descibed, and then the simpler operations for the removal of mechanical obstructions are detailed. An important chapter is that on ano-rectal fistula, and the subject of hæmorrhoids is carefully considered. The author describes a modification of Whitehead's operation, which he has found very satisfactory; it really consists in excising each hæmorrhoid separately and suturing the cut edges together.

Probably the most difficult subject in the surgery of the rectum is the question of the operation to be chosen in removing malignant disease of this portion of the bowel. The author speaks very favourably of a modification of Kraske's operation, by which the portion of the sacrum below the fourth sacral foramen is separated from the rest of the bone and turned to one side, to be replaced in position at the close of the operation. He has never met with necrosis of the portion of bone resected, but he acknowledges that the operation brings with it a large amount of shock. The chief merit of this method of operation is, in his opinion, that it involves injury to the sacral nerves and lateral sacral arteries on one side only. He holds that it is always possible to get sufficient of the bowel down from above to suture to the margin of the anus, and therefore he never finds it necessary to make a sacral anus. He does not consider that the abdominal or combined routes are often indicated.

On the whole, this work is good. The only real criticism to be made on it is that the author is somewhat too prone to quote verbatim the opinions of others, rather than to express the opinions which he has himself formed.

Practical Anæsthetics. (Oxford Medical Publications.) By H. EDMUND G. BOYLE, M.R.C.S. Eng., L.R.C.P. Lond., Assistant Anæsthetist to St. Bartholomew's Hospital; Demonstrator of Anæsthetics to the Medical School of St. Bartholomew's Hospital, &c. Second edition. With illustrations. London: Henry Frowde and Hodder and Stoughton. 1911. Pp. 209. Price 5*s.* net.

Mr. Boyle's text-book has already made a place for itself. It is now enlarged by the addition of a chapter on spinal analgesia and by fuller treatment of the administration of open ether. The chapter on spinal analgesia is not very full, and Mr. Boyle does not, we think, sufficiently differentiate between the value of high and of low punctures. He rather leads his readers to place them on the same level of usefulness, an opinion which we do not imagine he holds himself, and which is certainly, we think, not held by the majority of anæsthetists in this country. His reasoning, however, as to the

selection of spinal analgesia in certain cases and its avoidance as a routine appears to us sound. Having included spinal analgesia, he might for the sake of completeness have added also a chapter on regional and infiltration methods.

In discussing the question of shock Mr. Boyle states that a deep degree of anæsthesia is safer for the patient than a light one. This is a position which many would assail; certainly it needs qualification. Where chloroform is the anæsthetic we believe the exact converse to be true. Sufficient anæsthesia, of course, there must be, but granted complete unconsciousness and absence of conjunctival reflex, then the more lightly the patient is under chloroform during an operation involving severe shock, the more certainly we believe will the circulatory and respiratory functions continue to be adequately performed. The justification for very deep anæsthesia as a preventive of shock we believe to be a relic of the impressions produced in by-gone days by severe reflex symptoms following upon an incision made during incomplete anæsthesia. Further on in his book Mr. Boyle proceeds to show admirably how a deep chloroform anæsthesia in itself imitates the phenomenon of shock. He will therefore, we are sure, agree with us that it is not a condition to be induced when shock is present or anticipated. Mr. Boyle treats of collapse as a terminal condition of shock. It is more often regarded as an analogous condition produced especially by loss of body fluids, shock being due to exhaustion of nerve centres. This is perhaps merely a theoretical question, and at any rate Mr. Boyle's practical directions for treating the conditions are very good, though the employment of strychnine where pure shock is concerned is, of course, deprecated by those who hold that explanation of the condition to which we have referred.

With regard to the use of open ether, of which the author gives a concise account, he approves of the preliminary use of morphine and atropine, but does not mention scopolamine, which is a drug very worthy of consideration in this connexion. He gives an accurate account of the well-known "Bart.'s" method of giving chloroform, one which we think is not to be preferred to the use of some firmer kind of open mask.

Applied Biology: An Elementary Text-book and Laboratory Guide. By MAURICE A. BIGELOW, Ph.D., Professor of Biology in Teachers' College, Columbia University; and ANNA N. BIGELOW, M.S., Teacher of High School Biology. New York: The Macmillan Co. 1911. Pp. 583. Price 6*s.* net.

THIS book is intended by its authors to serve as a combined text-book and practical guide for a year's course of five hours a week. Its scope is wide enough, for it attempts to select from the fields of botany, zoology, and human biology the essential facts, and especially the great ideas, of the science of life which are of interest to the average intelligent person who has no time and reason for more extensive study of biology. The authors have accumulated and set forth in an orderly fashion such a mass of facts—including an account of experiments to demonstrate these facts—that "a year's course" rather understates the case. The authors' outlook is both wide and philosophic, for in its purview it includes the ideas of biology as they apply to human life in its combined intellectual, æsthetic, economic, and hygienic aspects.

Part I. deals with introductory matter and the Principles of Zoology, including such trite subjects as changes and composition of lifeless and living matter, the characteristics of living things, the structure and life of an animal—the frog being taken as the type—the structure and life of a plant with the bean as a type. A comparison of animal and plant biology follows and also a classification of animals and plants. It would appear that there is a "Teachers' Manual of Biology" which is designed to accompany this book, but it has not reached us. There is a concise paragraph on the "justifiable use of animals for science study." We can hardly consider the following a correct or adequate description: "The posterior, conical, whitish part of the frog's heart is called *ventricle*." Some of the physiology is of doubtful character. No indication is found of the size of milk globules (p. 47), while the figure of "a nerve cell and its fibers" can hardly be recognised as typical.

Part II. deals with Principles of Biology, illustrated by Types of Plants, beginning with an excellent and graphic account of "seed-plants," and ending with an attractive description of "spore-plants." In studies of spore-plants, while Pasteur's experiments on yeast are mentioned, the name of C. de la Tour finds no place. Why is not the exact formula of the sugar and other constituents in Pasteur's solution given? In the section on bacteria we looked in vain either in text or index for the name of Lister, while Koch's name is associated in the index with malarial organisms, the compiler of the index never apparently having looked at p. 291, whereon is recorded Koch's salient discovery of the tubercle bacillus.

Part III. deals with Principles of Biology, illustrated by Types of Animals, Invertebrate and Vertebrate, in which a very readable account is given of the subject. The economic relations are interestingly set forth, and it will come as a surprise to many to learn that "Grasshoppers destroyed crops to the value of $200,000,000 in Iowa, Missouri, Kansas, and Nebraska in four years." The statement that "the alimentary canal is essentially the same in all birds" (p. 432) is incorrect. In regard to the respiratory power of birds, we failed to find a reference to the size, number, and superficial area of their red corpuscles.

In Part IV. Principles of Biology applied to Human Structure and Life are introduced in an attractive form.

The book will prove useful and suggestive both to students and teachers of biology in its widest aspects. Most of the illustrations are taken from well-known authorities.

Dental Anæsthetics: A Text-book for Students and Practitioners. With a Contribution on Analgesia by JOHN BOLAM, L D.S. Edin., Honorary Assistant Dental Surgeon, Newcastle-upon-Tyne Dental Hospital. By WILFRED E. ALDERSON, M D., M.S. Durh., B.Hy., D.P.H., Honorary Physician, Newcastle-upon-Tyne Dispensary; Senior Honorary Anæsthetist, Newcastle-upon-Tyne Dental Hospital; Lecturer on Dental Anæsthetics, Newcastle-upon-Tyne Dental School. Bristol: John Wright and Sons, Limited; London: Simpkin, Marshall, Hamilton, Kent, and Co., Limited. 1911. Pp. 100. Price 2*s.* 6*d.*

THIS little book is a *résumé* of Dr. Alderson's lectures to dental students. The compression into brief dogmatic subdivisions which renders the subject matter easily available for reference on any individual point, makes at the same time for uncomfortably jerky reading. It is doubtless inevitable in a little work of this kind. Dr. Alderson is commendably emphatic upon the undesirability of using chloroform for dental operations. As he well points out, these operations are never operations of absolute necessity, and therefore it is never justifiable to run any risks with the anæsthetic. We think he might with advantage have bestowed more attention upon the continuous use of nitrous oxide and also upon details in connexion with dental ether cases, such as the proper use of sponges, designed to obviate the occurrence of after-sickness. Again, in his consideration of contra-indications to the use of nitrous oxide we should have liked to see special mention of cellulitis of the neck with some œdema of the glottis, a condition in which the use of nitrous oxide is highly inadvisable, and in which it is

likely to be suggested, owing to the presence of carious teeth as a suspected cause of the cellulitis. Dr. Alderson's general instructions are sound, and particularly we welcome a passage in which he points out the inadvisability of allowing the responsibility of choosing the correct anæsthetic to fall upon a man who has had solely a dental training. A useful chapter upon analgesia by Mr. John Bolam concludes the book, and will be not the least of its attractions for the dental student.

Die Lehre von der Krebskrankheit von den Aeltesten Zeiten bis zur Gegenwart. Von Sanitätsrat Dr. JACOB WOLFF, prakt. Arzt in Berlin. II. Teil, mit einer Abbildung im Text. Jena: Gustav Fischer. 1911. Pp. 1261. Price, paper, 26 marks; bound, 39 marks.

THIS is the second part of a great work on malignant disease, in which the author has gathered together all the knowledge of cancer from the earliest times to the present date, and has digested it so that now it forms a well-arranged whole. The first volume was concerned mainly with the general aspect of malignant disease, while in the present part the malignant affections of special organs are dealt with as well as the question of the biological and clinical etiology of cancer. The important subject of precancerous conditions is discussed, and the relation of malignant disease to other conditions is reviewed. The varieties of malignant disease are described. Chapters are devoted to the manifestations of the disease, metastases, recurrences, and its metabolism. After discussion of the general diagnosis, the remainder of the volume is concerned with the cancer of individual organs.

Criticism of a work such as this is impossible in any detail. It is vast, thorough, and complete, and all readers must acknowledge the industry and the energy of the author, and appreciate the value of the work he has carried out in providing surgeons and pathologists with so useful a summary of our knowledge of malignant disease.

A Manual of Fevers. By CLAUDE BUCHANAN KER, M.D. Edin., F.R.C.P. Edin., Medical Superintendent, City Hospital, Edinburgh, and Lecturer on Infectious Diseases to the University of Edinburgh. London: Henry Frowde and Hodder and Stoughton. 1911. Pp. 314. Price 7*s.* 6*d.* net.

THIS manual is intended for the use of students who are taking the prescribed course of study of the infectious fevers at an isolation hospital, and is written with a view to supply the theoretical and systematic information necessary for the full use of the practical opportunities afforded by the cases in these hospitals.

The first chapter of the work is introductory in character and is devoted to a brief but clear statement of the general nature of infection, immunity, and the febrile state. The second chapter contains useful descriptions of rashes and hints in regard to the examination of the skin and of the throat. The various rashes are classified into three groups—the erythematous rashes, those the elements of which contain lymph or pus, and the hæmorrhagic eruptions. The importance of examination of the throat as a routine measure in all sick children is forcibly emphasised, and the method of carrying out this procedure most effectively without frightening or hurting the child is described.

The individual fevers are then considered in separate chapters in the following order—measles, rubella, scarlet, fever, small-pox, vaccinia, chicken-pox, typhus fever, enteric fever, diphtheria, erysipelas, whooping-cough, mumps, and cerebro-spinal meningitis. Each disease is described systematically from the clinical standpoint, full accounts being given of the symptoms and their variations, of the course of the fever, and the nature, distribution, and effects of the rash. Diagnosis and treatment are also discussed in a thoroughly clear and practical manner. Short paragraphs are given describing the morbid anatomy, the blood changes, and where this is known the nature and character of the infective agent. The descriptions given are in simple language and are not mere transcriptions of text-book accounts, but are obviously based upon a large personal experience. They are illustrated by a few plates and by numerous reproductions of typical temperature charts.

The book should well serve the purpose for which it is written, and should also justify the hope expressed by the author in his preface that it may not cease to be useful when its owner has entered upon general practice.

The Law Relating to Medical Practitioners and Dentists in Great Britain, with an Appendix of Statutes. By J. N. MORTON, M.A., Solicitor, Secretary of the Western Medical School, Glasgow. London and Edinburgh: William Green and Sons. 1912. Pp. 148. Price 7*s.* 6*d.* net.

Mr. Morton has compiled a brief exposition of the law relating to the medical profession, in the form of a series of paragraphs grouped in chapters and followed by explanatory notes illustrated by reference to cases. These are followed by an appendix consisting of the Medical Acts, the Anatomy Acts, and the Dentists Act, 1878, and an index. There is also a table of contents and an index of reports and abbreviations.

The subject is one upon which, so far as we are aware, no good modern text-book exists, and the writer has the advantage of familiarity with the Scottish law relating to it, but at the same time the law, so far as it immediately concerns medical practitioners, comprises, in our opinion, a good deal more than can readily and usefully be compressed into 150 octavo pages; so that a work dealing with it, to be really satisfactory, should contain information upon topics which Mr. Morton has not dealt with at all. His opening paragraph, which apparently contains all that he has to say as to the use by the unqualified of titles implying qualification, is an example of brevity which is, to say the least, excessive. Among omissions it may be mentioned that the chapter on medical men as witnesses contains no statement of the fees fixed for them by regulation in criminal cases in England, nor do we find any reference to their appearance before coroners.

Interne Klinik der Bösartigen Neubildungen der Bauchorgane. Von Priv.-doz. Dr. RUDOLF SCHMIDT, K.K. Primararzt am K.K. Kaiserin Elisabeth-spital, Wien. Mit einer farbigen Tafel. Berlin und Wien: Urban und Schwarzenberg. 1911. Pp. 355. Price, paper, 12 marks; bound, 14 marks.

FEW diagnoses are of greater importance than those connected with the nature of an abdominal swelling. On the one hand, the belief that a malignant tumour is merely inflammatory in nature may induce the surgeon to allow the time to pass by when operative interference might have been undertaken with a good hope of success; while, on the other hand, to diagnose a simple inflammatory swelling as a malignant growth will in the first instance cause much unnecessary pain to the patient and his relatives, and later may lead to a useless laparotomy. The importance of this decision is, however, almost equalled by its difficulty, and therefore it behoves medical men to devote much care to this matter.

This book has been written mainly with the purpose of assisting in the diagnosis of abdominal diseases, and it appears to be very well suited for its purpose. The first 60 pages are devoted to general considerations, such as the external examination, the internal examination, and the

use of the Roentgen rays and the "diazo" and "aldehyde" reactions of Ehrlich. The several organs are then taken in order, and in each case the early symptoms of malignant disease are detailed; the physical examination of the organ is described; then the course and duration of the condition, and, lastly, the differential diagnosis are given. The latter half of the volume contains reports of a large number of cases that have been under Dr. Schmidt's care. These should prove very useful in assisting the reader to appreciate the points on which a diagnosis is based.

The book is well written, but we should have preferred more illustrations. There is, it is true, an excellent coloured plate showing the bacteria present in a number of conditions, but the volume contains no other illustration.

Medici e Ispettorato del Lavoro. (Publication of the Permanent International Committee for the Study of Industrial Diseases, Milan.) By Dr. LUIGI CAROZZI. Cusano: A. Colombo e Figli. 1911. Pp. 176.

THE author of this work on the Medical Inspection of Factories has been secretary of the Permanent International Committee for the Study of Industrial Diseases since its formation in 1906, having its headquarters now, with library and laboratories, in the Clinic for Industrial Diseases in Milan. Dr. Carozzi has studied his subject deeply in Belgium and England, where the value of medical inspection in factories has been recognised for many years. Germany in this respect has lagged behind, although in Baden and Würtemberg—but not in Prussia—medical appointments in the factory departments have been made within the last few years. Holland and Austria, also, have recently made similar whole-time appointments. In France and Prussia systematic medical intervention in factories appears to be limited to periodical medical examination of workers in a few specially dangerous trades. Belgium has had four medical inspectors of factories since 1905, with, as their chief, Dr. D. J. Glibert, whose scientific outlook on the problems confronting him has influenced continental opinion not a little in favour of the Belgian system.

Dr. Carozzi, however, deals not only with the activities of permanent officials, but also with the duties and functions of certifying and appointed surgeons (*médecins agréés*). The certifying surgeons in this country, he says, represent "la forza incondizionata" of the medical service. But it is evident that his ideal is the full-time factory surgeon independent of everybody but the State, and working in association with a laboratory and clinic for occupational maladies and accidents. Before this can be reached, however, he recognises that much more prominence must be given to the subject in the medical curriculum than is the case at present.

The author treats his subject in each of the principal countries of Europe historically. Mention is made of all the principal enactments creating or extending the duties of medical men in regard to industry, and there is a useful bibliography, not only of the subject generally, but also of the individual researches of the various medical inspectors of factories.

Traitement adjuvant du Strabisme. Par F. TERRIEN et HUBERT. Paris: G. Steinheil. 1912. Pp. 292. Price 4 francs.

THIS is one of the best of the many small monographs on squint which have appeared.

The book commences with a general discussion of the subject, and describes the manifestations of squint, its nature and evolution. Its cerebral origin is asserted, and adjuvant factors, such as errors of refraction, are allotted their appropriate sphere. In dealing with convergent strabismus, the indications for atropine are discussed, and its application to the fixing eye, in order to prevent the development of amblyopia in the squinting eye or to improve its vision by exercise, is rightly advocated. Occlusion of the fixing eye with the same object is recommended as an alternative treatment, correction of hypermetropia by glasses receiving adequate attention. A chapter on divergent strabismus deals briefly with the myopic element commonly present, and discusses the use of prisms and tenotomy of the external recti. A chapter on astigmatism and anisometropia follows, thus completing the preliminary excursus and leading up to the main subject matter of the book—viz., the relation of squint to binocular vision and the orthoptic treatment of the disorder.

Orthoptic exercises are introduced by an excellent account of Rémy's diploscope and its various uses, followed in logical sequence by Javal's bar reading, Worth's amblyoscope, the synoscope and the stereoscope. These subjects are all familiar, with the exception of the synoscope, an instrument introduced by the authors. It may be regarded as a further development of the principles of the diploscope, and appears to us thoroughly to justify its existence as a simple and valuable instrument for orthoptic treatment. The various steps in the treatment of a case of convergent squint—the development of simultaneous vision, the fusion of the double images, the establishment of binocular vision and its gradual improvement by diploscopic and other exercises—are lucidly described. After a short chapter on the orthoptic treatment of divergent strabismus the use of the stereoscope is discussed.

We can confidently recommend the book as an admirable introduction to the rational treatment of squint.

Lehrbuch der speziellen Chirurgie. Von HERMANN TILLMANNS, Dr. Med. et Sc., Geheimer Medizinalrat und Professor an der Universität Leipzig, Generalarzt à la suite des Königlich Sächsischen Sanitätskorps. Neunte, verbesserte und vermehrte Auflage. Part I.: Pp. 888, with 647 illustrations. Part. II.: Pp. 1079, with 783 illustrations. Leipzig: Veit and Co. 1911. Price, paper, 50 marks; bound, 55 marks.

Tillmanns's "Surgery" has occupied for many years a very prominent position in German surgical literature, and its English translation has had a large circulation in this country and in America. It is hardly necessary to add that the work is fully deserving of the reputation it possesses. The volumes which we are now noticing constitute the special part of the "Surgery," as "General Surgery" forms a separate volume.

The present issue of the special part of the work has undergone a very complete revision in order to bring it completely up to date; many chapters have been rewritten, and in many ways it is almost a new book. Some of the older illustrations have been withdrawn and many new ones have been added. On the whole, the illustrations are very good and clear, but some of them are on a small scale, which renders them less useful than they would otherwise be; this applies mainly to some of the older blocks which date from the earlier issues. A few of the illustrations are in colours, and these are especially good. The characteristic of the work has always been that it contains a full account of the various branches of surgery, giving the chief prominence to the most important subjects, but without neglecting the less employed methods of treatment.

The favour with which earlier issues have been received should be extended also to this edition, for it is equally well deserved.

LIBRARY TABLE.

Case Histories in Medicine, Illustrating the Diagnosis, Prognosis, and Treatment of Disease. By RICHARD C. CABOT, M.D., Assistant Professor of Clinical Medicine, Harvard Medical School. Second edition, revised and enlarged. Boston: W. M. Leonard. 1911. Pp. 295. Price $3.00.—In the second edition of this book Dr. Cabot has gone more into details as regards prognosis and treatment than in the previous edition. The order of the cases has been changed by grouping them under the headings of Infectious Diseases, Gastro-intestinal and Biliary Tract, Urinary Tract, Circulation, Respiratory System, Nervous System, Lymphatic and Ductless Glands, and Diseases of Unknown Origin. Each clinical case is briefly stated in all its important features, and certain questions arising therefrom are formulated and answered. The value of each point noted is then discussed and a diagnosis is suggested. The prognosis and treatment next receive consideration. The author expresses the hope that he will continue to be aided by the frank criticism of those who differ from him in regard to his diagnosis, prognosis, or treatment. A very interesting note on drug therapy has been added, to refute the charge of therapeutic nihilism so often levelled against medical teachers. The author discusses therein the present outlook for drug therapy, placebos, the homœopathic principle and modern dosage, and presents a working list of drugs drawn up on the basis of those actually used by the physicians of the Massachusetts General Hospital staff during the past four years, 50,000 prescriptions having been scrutinised for the purpose. We repeat that the book is likely to prove useful both to students and practitioners.

Aids to Ophthalmology. By N. BISHOP HARMAN, M.A., M.B. Cantab., F.R.C.S. Eng., Lecturer in Ophthalmology, West London Post-Graduate College. With 100 illustrations. Fifth edition. London: Baillière, Tindall, and Cox. 1912. Pp. 216. Price, 2*s.* paper, 2*s.* 6*d.* cloth.—The fifth edition of this book has undergone a thorough revision. A table of contents and some 60 new illustrations have been added. The subjects of glaucoma, optic neuritis, and muscle balance have been allotted more space, while the subject of refraction now occupies seven chapters. A chapter on ocular therapeutics has also been added. So long as this and similar works are not regarded as text-books, but are used for review only, they will fulfil a useful purpose for the student and the general practitioner.

Life, Death, and Immortality. By W. HANNA THOMSON, M.D., LL.D. New York and London: Funk and Wagnalls Company. 1911. Pp. 117. Price $1.00 net.—The author of this little book on a great subject is past president of the New York Academy of Medicine, and has already written on the deep questions of life and personality. In little over a hundred pages it is not to be supposed that the treatment of such subjects can be other than introductory and stimulant to further study. This is apparently what Dr. Thomson has aimed at, and he has succeeded, his familiarity with psychology and psychological medicine giving him a deeper insight than that possessed by the ordinary physician. He traces the beginnings of life on the earth and the development of the personal being, man; shows the impossibility of explaining the development and growth of organised beings as the result of chance; and just hints at the hereafter. It may be doubted if that division of the kingdom of life that consists of microscopic unicellular organisms is "characterised by the greatest variety of distinct and permanent species" (p. 74); one would be more inclined to say that permanence is not the characteristic of bacterial "species," if by permanence is meant immutability. This, however, in no way affects the author's argument. Although, perhaps, there is nothing absolutely novel in Dr. Thomson's views, the manner of treatment is so attractive and the exposition so clear, and in the best sense of the word popular, that the book may be read with interest and profit by everyone. It is stimulating and refreshing.

Circumstances or Character? Studies in Social Work. By CLEMENT F. ROGERS, M.A. London: Methuen and Co., Limited. 1911. Pp. 218. Price 3*s.* 6*d.* net.—The author has collected a number of papers and addresses that he has written or delivered during recent years on various aspects of social work. He is a strong supporter of the Charity Organisation Society, and his object has been, in part at any rate, to justify its aims and methods. After an introductory section on fundamental principles, he treats of charity and the Church briefly but adequately from the historical point of view. Beginning with the short but significant references that are found in the New Testament, from which we learn that widows and orphans, the sick and the aged, and prisoners were cared for, Mr. Rogers traces the defective methods and encouragement of beggars that became general in the Middle Ages and after. An interesting chapter collects some references in eighteenth century literature to charity in England; it practically merely meant, as a rule, the giving of doles, which Mr. Rogers, of course, emphatically condemns. We think, however, that he is not just to Miranda, the heroine (or one of the heroines) of Law's "Serious Call," who, according to Mr. Rogers, did "everything that the Charity Organisation Society holds to be anathema." The point of view in those days was, no doubt, different from ours, but, at any rate, this benevolent lady not only gave away her money but employed her time in personal investigations as to the recipients of her charity; she set up poor tradesmen in business, put poor children in the way of employment, and comforted poor people who were too old to work, all being done in her own neighbourhood, where she knew the circumstances. That she did it, as Mr. Rogers says, "without discrimination" is his gratuitous supposition. In this same eighteenth century that our author rather girds at we find Fielding, in his "Covent Garden Journal," denouncing the giving of money to beggars as "a crime against the public," and in his well-known "Inquiry into the Late Increase of Robbers," dividing the poor into three classes—those unable to work, those able and willing, and those able but not willing, and prescribing appropriate treatment for each. The difficulty, he wrote, is the method of adapting—i.e., the bringing the workers and the work together. This is one of the chief objects of the Charity Organisation Society to-day, but it was also advocated in the despised eighteenth century by Fielding, who did other things besides write "Tom Jones." Mr. Rogers justly calls attention to the "almost complete ignorance of the work of the friendly societies" on the part of the clergy and of the feeling of irritation that this naturally gives rise to, and he mentions, only to condemn, the spurious form of thrift called "slate clubs," often supported by the clergy in ignorance of the injury they do to the *bonâ fide* friendly societies. There is much also worthy of attention in his outspoken remarks about free dinners to poor children and kindly but sometimes careless dispensation of free boots, and other help in kind. "The gradual breaking down of character by the expectation of help, whether private or from the rates, is becoming a national danger," he says roundly. Lastly, in a review of the organisation of charity, the author shows how we may learn from the Socialist, Individualist, Communist, and Liberal, but the Socialist who merely insists on his rights is as odious as the Individualist who is merely selfish. Mr. Rogers has a wide knowledge of his subject, and his book will be of value and

will give ideas to all who are interested in, and work with and for, "the poor." The gist of the matter is that "the cure of distress lies in character, in the character of the workers, in the character of those in distress."

MISCELLANEOUS VOLUMES.

THOSE who desire to enter on the study of eugenics—the consideration from a biological point of view of problems concerning social organisation, population, and the future welfare of the race—would do well to take their first steps under the guidance of *An Introduction to Eugenics*, by WILLIAM CECIL DAMPIER WHETHAM, M.A., F.R.S., and his Wife, CATHERINE DURNING WHETHAM (Cambridge: Bowes and Bowes; London: Macmillan and Co., Limited; Glasgow: James Maclehose and Sons. 1912. Pp. 66. Price 1*s.* net). The authors rightly say that "as in all branches of science, a knowledge of the range and methods involved in the inquiry is the first requisite to a clear understanding of the subject." This admirably concise yet explicit little pamphlet briefly unfolds the history of eugenics, discusses racial qualities, describes the methods of research, and examines the construction of society. The appendix and bibliography deserve special praise; the latter consists of no mere string of books and articles, but points out briefly the scope and character of some of the principal works by eminent authors bearing directly or indirectly on the subject.—Those interested in witchcraft, possession, spectres, and such-like ghosts that, despite the exorcism of latter-day civilisation and knowledge, decline to be altogether laid, may possibly be interested by two recent books. In *Demoniacal Obsession and Possession as Causes of Insanity* (London: The Ambrose Company, Limited. 1911. Pp. 51. Price 1*s.* net), Mr. C. WILLIAMS, L.R.C.S., L.R.C.P. Edin., essays in 51 pages to prove that demoniacal possession is a fact, and that it is manifested in certain kinds of insanity, of which it is the cause. He bases his belief in the reality of possession on the assertions that the Christian religion teaches us to expect it and that he has *seen* it (author's italics).—Dr. J. MAXWELL WOOD, in *Witchcraft and Superstitious Record in the South-Western District of Scotland* (Dumfries: J. Maxwell and Son. 1911. Pp. 355), recounts the results of his gleanings on witchcraft, fairy-lore, death-warnings, funeral ceremony, and ghost story, from Dumfriesshire and Galloway, without attempting to subject them to higher analysis or criticism, as adequately presenting "a truer aspect and reflection of the influence of superstition upon the social life of those older days." The book is a distinct addition to Scottish folk-lore.—The mental wanderings of souls unfettered by the shackles of time or space are recounted by Mr. G. M. IRVINE in his book *In the Valley of Vision* (London: Simpkin, Marshall, Hamilton, Kent and Co., Limited. 1911. Pp. 155. Price 2*s.* 6*d.* net). "Dr. Semel Bis" having acquired the art of telepathically reading these flights of fancy in his patients "when in a critical condition as the result of acute disease," records them in a manner that somewhat ingeniously illustrates the determination given to delirium by the problems, pursuits, or natural characteristics of the subject. Morals, philosophy, and fantasy are intermingled in a kaleidoscopic phantasmagoria.—"*Truth*" *Cautionary List for 1912* (London: *Truth* Publishing Co. Pp. 124. Price 1*s.*, by post 1*s* 2*d.*) continues its knight-errant career as a protector of the gullible public. Pp. 44–52 of this issue are devoted to comment on certain alleged medical quackeries. Perhaps the most inherently vicious of these are certain advertised cures for drug habits which surreptitiously supply the bane under cover of providing an antidote.

JOURNALS AND MAGAZINES.

The Journal of Physiology. Edited by J. N. LANGLEY, Sc.D., F.R.S. Vol. XLIII., No. 5. Dec. 22nd, 1911. London: C. F. Clay, Cambridge University Press. Price 4*s.*—G. C. Mathison (Beit Memorial Research Fellow), working under the direct guidance of Mr. Barcroft, of Cambridge, has investigated "The Influence of Acids upon the Reduction of Arterial Blood." That organic acids, such as lactic acid, are present in the blood in asphyxia and after violent exercises has been abundantly established. Lactic acid occurs in the tissues in conditions of deficient oxidation, and the importance of organic acid in tissue respiration is acknowledged. This research follows the lines already so successfully laid down by Mr. Barcroft. Blood completely saturated with oxygen is exposed to an atmosphere of nitrogen, either by an aerotonometric method or by bubbling a stream of nitrogen through a quantity of blood. A simple method was ultimately devised whereby from 3 to 5 c.c. suffice to test quantitatively the rate of reduction of arterial blood by the passage of a current of nitrogen. Lactic, acetic, formic, carbonic, hydrochloric, and sulphuric acids hasten the rate at which arterial blood gives up its oxygen at low tensions. The accelerating effect of carbon dioxide and other substances is mainly due to the change in hydrogen ion concentration produced by them. The next paper, by Soroku Oinuma, on the "Relative Rates of Oxidation and Reduction of Blood," continues the study of the gases of the blood as devised in the Cambridge School. The rate of reduction of blood is greatly increased, and the rate of oxidation somewhat retarded, by a rise of temperature. The rate of oxidation of blood by alveolar air is about twice that of a similar mixture containing half the quantity of oxygen. The contribution by D. H. de Souza on "Protection of Trypsin from Destruction by Heat" occupies about five pages, and deals with the question from a laboratory point of view. A. V. Hill deals with the "Total Energy Exchanges of Intact Cold-blooded Animals at Rest." He used four types of cold-blooded animals—viz., frogs, newts, worms, and snakes. In the summary of results confirmation is obtained of a fact already well known, that the animal "regulates its own metabolism" independent of the O_2 tension. He further finds that "the heat production of men and big animals is probably not due to a special mechanism, but is merely a direct consequence of the activities of living cells." The next communication, by Casimir Funk, on the "Chemical Nature of the Substance which Cures Polyneuritis in Birds Induced by a Diet of Polished Rice," occupies six pages, and is from the Lister Institute. Its author starts from the statements of several observers that the cortical layers of rice contain a substance which cures both the beri-beri in man and the polyneuritis which is produced in birds by feeding them on polished rice. The author carried out his experiments on pigeons with a view to determine the nature of the "curative substance." Physiological chemists will be interested in the details of the author's methods. It appears that the polyneuritis of birds is due to lack of an "essential substance" in their diet—a substance which is absent in polished rice and is contained in rice polishings.[1] The curative dose of the active substance is small. The following are some of the titles in the Proceedings of the Physiological Society, Nov. 18th, 1911: F. H. A. Marshall, On the Ovarian Factor concerned in the Recurrence of Œstrus; A. R. Mines, Interpretation of the "Protective Action" of Gelatine on Colloidal Gold; A. F. Stanley Kent, The Influence of Salts upon the Action of Rennet on Milk.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 24, 1912.

The National Insurance Act.

WE publish elsewhere an account of the meeting of the Representatives of the British Medical Association, which took place in the Guildhall, London, on Tuesday, Wednesday, and Thursday last. The meeting was held with the object of considering the report of the Council of the Association on the relations of the medical profession to the National Insurance Act, in which report the Council made the recommendations which will be found printed in full in THE LANCET of Feb. 3rd, p. 335, and which have also appeared in publications of the British Medical Association, as well as in the lay press. The recommendations of the Council, it will be remembered, asked for instructions to press upon the Government the necessity of further conditions to secure the requirements of the profession, and to notify the Insurance Commissioners that no negotiations will be entered into with any Insurance Committee until the Representatives are satisfied; to submit a report upon the regulations when issued by the Insurance Commissioners; to make certain arrangements for appointing provisional medical committees in every insurance area; to take steps against the possibility of medical attendance being obtained at inadequate rates; and to appoint a new State Sickness Insurance Committee to consider and report to the Council on all matters connected with the Act. This represents the pith of the recommendations. The Council, to put it briefly, asked the constituencies, through their delegates, to work the Act on the understanding that the medical profession was secured by further provisions against the many risks and possible wrongs which have been so freely pointed out during the last eight months. The Representatives, however, as was confidently expected, decided that the report of the Council seemed to put too favourable a construction upon the Act. The net result of the meeting is that the recommendations of the Council of the British Medical Association have been considerably strengthened, and that the Association has declared that it will call upon the profession not to work the Act unless the minimum demands of the profession are effectually and permanently embodied by the Commissioners in the Regulations, with a view to their subsequent incorporation in an amending Act. Although motions to break off all negotiations, and to demand an immediate amending Act, were lost, yet the reform party of the British Medical Association and the National Medical Union at this meeting of Representatives made good their views to a considerable degree. Moreover, the two opposing sections within the Representative Body managed to sink their differences, and by mutual concessions gave a unanimous vote upon the above vital declaration of policy. We regard this as a really hopeful sign of approaching unity in purpose and in action within the ranks of the profession, and we are glad to think that the demand for Regulations containing definite guarantees was first proposed in the columns of THE LANCET. The next step should be taken by Mr. LLOYD GEORGE and the Insurance Commissioners. It remains to be seen whether in the circumstances now created the Chancellor will realise the necessity of coming to an understanding with the medical profession.

Epidemic Poliomyelitis.

THE Local Government Board issued last week a volume of Reports and Papers on Epidemic Poliomyelitis, prefaced by an introduction by Dr. A. NEWSHOLME, which promises to be of great utility to those concerned with the disease in its various aspects in this country. The volume comprises a summary, prepared by Dr. HUGH A. MACEWEN, a digest of whose contents we published last week, of the principal facts which have been recorded in the extensive literature of the subject in Sweden, the United States, and other countries where poliomyelitis has been epidemic on a wide scale during recent years, and a review by Dr. M. H. GORDON of the results obtained to date by Professor LEVADITI and other workers in foreign laboratories who have investigated the virus of poliomyelitis and its experimental transmission from man to animals and from animals to animal. It also sets out the results of inquiries made for the Local Government Board by Dr. R. A. FARRAR in the Midlands and in Dorsetshire in 1910, and by Dr. R. J. REECE in Devon and Cornwall in 1911. Dr. REECE'S report establishes the fact that the disease not only showed a considerable prevalence in one or two places, especially Holsworthy, but that cases, singly or in small groups, were scattered widely over both counties. It is probable that if any other part of England had been as systematically worked last summer a very similar result would have been obtained. Dr. REECE'S inquiries have also confirmed the foreign experience that poliomyelitis occurs to a disproportionate extent in remote country places and isolated dwellings, and as a result of his painstaking investigations it can be said that epidemiological considerations similar to those frequently ascertained in Sweden and America also arise in this country and equally await explanation. Dr. REECE'S paper will be a little disappointing, perhaps, to those who have formed no clear idea of what its scope would be. It does not contribute much new knowledge with regard to the clinical character or the pathology of the disease; while it is guiltless of novel or startling theory. But this should not surprise us. It could hardly be expected that all the circumstances of an epidemic widely spread, not compulsorily notifiable, and often difficult of diagnosis, could be worked out satisfactorily from every point of view by one observer, whatever his practical

experience in the clinical or the epidemiological investigation of this disease; or that such an inquiry should at once place us in advance of other countries, where the disease has been much more extensive and where many observers have had several years of experience and numerous co-workers and assistants in inquiring into epidemics of this nature.

Among the 154 cases reported by Dr. REECE as poliomyelitis in the Devon and Cornwall outbreak are certainly some which from clinical description alone would hardly be accepted as cases of poliomyelitis, undue stress being laid, we think, on certain signs, while little mention is made of others which are of considerable significance. For instance, importance seems in the report to be attached to the presence of Kernig's sign, and yet it is generally regarded as a sign of small diagnostic value. That portion of the report which is concerned with the epidemics at the village of Stoke Rivers is particularly satisfactory from the epidemiological point of view; it has been worked out with the greatest care, and in detail, with the result that there must be considerable doubt whether that epidemic was one of poliomyelitis. What the nature of the poison was which gave rise to the epidemic remains doubtful, and this very fact emphasises the necessity there is for obtaining some clinical test or some serum reaction by which the uncertain and abortive cases of poliomyelitis may be recognised. The report of the epidemic in the Midlands in the summer of 1910, which follows upon Dr. REECE'S report, is of interest, for it shows that cerebro-spinal meningitis and poliomyelitis may, as has always been recognised, coexist; but, as Dr. FARRAR points out, these are two distinct diseases, and their coexistence does not indicate any relationship. In a community in which cerebro-spinal meningitis is a notifiable disease it is certain that from time to time cases of tuberculous and septic meningitis, and also cases of the cerebral form of poliomyelitis, will be notified. The examination of the cerebro-spinal fluid in such cases is essential, for from its cytological and bacteriological characters a correct diagnosis can always be made. The epidemic at Cerne Abbas in Dorset is most instructive, in that it shows the variability of the infectivity of the virus. In this small epidemic of 16 cases, three children were infected in one house; on the other hand, a father contracted the disease and remained in a small cottage with his wife and several children, not one of whom developed the disease. Whether the freedom from infection in this latter family can be attributed to the use of permanganate of potash gargle must remain doubtful; but it is certainly a simple and harmless preventive measure.

It is to be hoped that the Local Government Board will regard the report now presented as a preliminary one, and will make arrangements as suggested in the preface by its chief medical officer for "further research both in the laboratory and by exact and painstaking inquiry into the circumstances of local outbreaks," so that any outbreaks of poliomyelitis which may occur during the coming summer may be thoroughly examined from every point of view. The lines on which further investigation should be carried out will have to be carefully thought out. The report of the Local Government Board has indicated one important line of investigation—viz., the possible relation of certain forms of illness in domestic animals with poliomyelitis. The experimental work of Dr. H. K. MARKS (to which Dr. F. E. BATTEN called attention in our columns last week, in the course of a lecture upon experimental poliomyelitis) has shown that rabbits injected with the virus of poliomyelitis often die suddenly from a disease which bears no clinical resemblance to poliomyelitis, but which, when again communicated to a monkey, reproduces the disease in its typical form. The Local Government Board may be congratulated on obtaining the assistance of Professor LEVADITI, of Paris, in carrying out its experimental investigations in the transference of the English virus to monkeys, but it is natural to wish that an English bacteriologist had been able to undertake the work. The more do we feel this because in future investigations of this disease it will be essential that the experimental work be carried on in this country.

The Teaching of Anatomy.

AT a recent meeting of the Southwark board of guardians, briefly reported in our issue of Feb. 10th, it was resolved that in future no unclaimed bodies of paupers should be sent to the schools of anatomy for dissection, and though a letter was read from Mr. F. G. PARSONS, the lecturer on anatomy at St. Thomas's Hospital, pointing out the importance of a knowledge of anatomy to medical students, the board decided to adhere to its resolution, one of its members adding that he was glad to learn that other boards of guardians, especially in the North of England, were following their example. We have only to say that if other boards of guardians are found in any quantity to subscribe to the views of the Southwark board a fatal blow at medical progress will be struck.

An adequate knowledge of anatomy can be obtained only by dissection. This must be the starting-point of any discussion on the question whether boards of guardians should grant for the study of anatomy or withhold the unclaimed bodies of paupers. On this point all who are acquainted with the position will agree; every teacher of anatomy or surgery, everyone who has to instruct students of medicine, must acknowledge that without a knowledge of anatomy it is not possible for the medical student to be adequately equipped. It is only by dissection, by seeing the tissues of the body in their natural positions, and in their relation to one another, that a student is enabled to learn, and learn thoroughly, the structure of that with which he has to deal afterwards when he practises his profession. Without an adequate knowledge of anatomy the medical practitioner will always be at sea; he will feel that he is not sure of the formation of the part which he is examining, and as a result both his powers of diagnosis and of treatment will be greatly impaired. His diagnosis will be faulty because he will be unable to appreciate the relation which the anatomy of the part concerned has with the symptoms manifested; his lack of knowledge will interfere seriously with his powers of treatment, especially with his capacity for operating, and either from fear of doing harm he will not venture upon

what is required, or, if his lack of knowledge fail to restrain his hand, he may inflict irreparable damage. It is incontrovertible that there is nothing more essential for the basis of the knowledge of the student of medicine than a real familiarity with the anatomy of the human body, and it may reasonably be asked what substitutes have been suggested for dissection. The use of plates, illustrations, and models may assist in perfecting the student's knowledge of anatomy, but it can never replace dissection. The anatomical knowledge obtained from books and plates may suffice for the passing of some of the less severe examinations in anatomy, but it will not serve for the practice of medicine and surgery. The skilled examiner can always distinguish between the student who has learned his anatomy from books and the student who has gained his knowledge from dissection. Those who oppose the use of the unclaimed bodies of paupers for dissection must either believe that a knowledge of anatomy is unimportant for the practice of medicine, or that a knowledge of the subject can be obtained in some other way. There is no method save dissection of obtaining a satisfactory knowledge of anatomy.

The feeling of sentiment that impels a board of guardians to refuse to allow the unclaimed bodies to be used for the teaching of anatomy is perfectly natural; they feel that as no friends or relatives are there to see that the bodies of these poor people are given decent burial, it behoves them as the trustees for the poor to see to it. They are possibly ignorant of the fact that all bodies sent to the medical schools are buried in consecrated ground with all due religious rites, and that the process of dissection has merely anticipated the normal effects of putrefaction without its horrible accompaniments, since the bodies are preserved with the strongest antiseptics. We cannot help thinking that if guardians knew how very essential it is that students should dissect, they would not allow a sentiment for the dead, however laudable, to override the needs of the living. No stigma attaches to the dissected body. At one time it was different, for it was part of the sentence on some criminals that when they had been hanged their bodies were to be handed over to the surgeons for dissection; so that ignominy attached to dissection. When, however, the Anatomy Act was passed in 1832, in order that this slur should be taken away, it was enacted that in future the bodies of executed criminals should not be dissected. The horrors of "body-snatching" were entirely due to the difficulties intentionally cast in the way of the supply of bodies for dissection. The examining authorities require a knowledge of anatomy which can be gained only by dissection; these examinations must be passed by anyone who wishes to practise medicine; it is clearly, therefore, the duty of the State to see that the schools of medicine are provided with sufficient bodies for the teaching of anatomy. In most of the provincial schools of medicine the difficulty is not so keenly felt, partly because the guardians seem more ready to recognise that dissection is essential for the due teaching of anatomy, and partly because the requirements are not so great as in London, where more medical students are to be found and where more examinations are held. A solution of the difficulty must be discovered. The simplest method of solving the difficulty would be to take from the boards of guardians the right of deciding what should be done with the unclaimed bodies of paupers; this would relieve the guardians of the expense of burying these unclaimed bodies, and would enable the schools of medicine to carry on their work efficiently. It has been suggested that it might be possible to import the bodies required, but the expenses would certainly be greatly increased. Whatever solution may suggest itself to those in authority, one thing at least is clear, something must be done to supply sufficient bodies for the instruction of our future physicians and surgeons. Many of those who are most bitterly opposed to the anatomical use of unclaimed bodies would be the first to complain if a medical man were to make a mistake in the diagnosis or treatment of themselves or their relatives, from a want of knowledge of anatomy.

Annotations.

"Ne quid nimis."

THE COAL STRIKE AND THE SANITARY SERVICES.

NEVER before probably in the history of this country has it been so sternly and acutely realised by us all to what an extent the great systems of our modern life depend upon our regular supply of coal. During the last fortnight the community has been aroused to the fact that a coal strike may quite possibly take place, and that the inadequate heating and lighting of our homes are absolutely trivial matters compared with the real terrors of such a ghastly disaster. Look at this one thing only—a prolonged coal famine would bring our principal sanitary schemes to a standstill. The splendid efficiency of our public health administration will be threatened with complete defeat if the supply of coal be discontinued. Our great schemes of water-supply and sewage disposal, for example, would fail, and such failures would bring disease and death in their train. Our water and sewage mains without the steam pumps would become an arterial system with a non-beating heart. When the railway strike assumed for a time a serious position last summer, it was reported that fears were entertained that the distribution of water in the metropolitan area was within sight of being stopped, as coal could not be got quickly enough to keep the engines of the great water pumps going. There was threatened a shortage because the means of communication between the colliery and the pumping stations were shut off, but fortunately a long strike was averted and a serious situation saved. It is to be hoped that again counsels of peace may prevail, though it is obvious that the struggle upon which the miners and coal-owners are engaged is a vastly greater one than that which so sadly affected the comfort of holiday-makers last year. It is difficult to think of any department of life that will escape catastrophe if a hard, determined policy of war is persisted in. The damage to the industrial interests of the country will of course be enormous. Misery or starvation will be experienced by thousands. But over and above this stands in our mind the risk that a great injury may be inflicted upon the public health machinery of the country which will take a weary time to repair. It is clear that a prolonged coal strike must mean a compulsory falling away from our present high sanitary standard, the maintenance of which is responsible for the splendid health statistics of the country. For that reason alone we may well pray for peace.

ANTIVACCINATION AND THE ENCYCLOPÆDIA BRITANNICA.

IN THE LANCET of Nov. 25th, 1911, we reviewed the article on Vaccination by Dr. S. Monckton Copeman in the new edition of the Encyclopædia Britannica. A "Reply"[1] to Dr. Copeman's article has been issued in pamphlet form from the headquarters of the antivaccinationists. It consists, for the most part, of the usual denials of everything that is well established to all except those who will not see. Naturally space is too valuable to keep on repeating the same categorical denial of "facts" which are not facts, but there are three points in the pamphlet which may be worth some comment. 1 After an ineffectual attempt to disprove the identity of small-pox with cow-pox, it is stated that "if the non-identity of cow-pox with small-pox is established, the alleged scientific basis of vaccination is at once exploded, as there is no evidence that one infectious disease is capable of setting up immunity against another." But the professional estimate of the value of vaccination is based on logical reasoning from observed facts, and not on any theory whatever as to how it works, though, of course, the settlement of that question is highly desirable. Further, to assert that there is no other known case in which one infectious disease is capable of setting up immunity against another would be, even if true, of no value as an argument that this particular disease does not do so, unless the assertion that it does were based on the theory that all infectious diseases do produce immunity against other infectious diseases—a foolish proposition which no one has made. Again, the author of the pamphlet adduces as evidence against the identity of the two diseases, the assertions that inoculation of small-pox into a cow does not produce cow-pox, that small-pox causes a general eruption, while cow-pox causes only a local eruption, and that small-pox is spread by infection as well as by contagion, while cow-pox is spread by contagion only. Yet in the face of these assertions he considers it "safe to say that there is little, if any, 'cow-pox' lymph in use to-day," because "small pox virus, cultivated through a series of calves, is now the favourite brand." Now, if small-pox does not produce cow-pox in a cow, what does it produce? For the condition induced in human beings by the lymph derived from "small-pox virus, cultivated through a series of calves," does not produce a general eruption but only a local one, and the condition in calves thus induced is not infectious to human beings, but must be inoculated to produce any result at all. As a matter of fact, the results of vaccination, whether, as formerly, from undoubted spontaneous cow-pox, or as (asserted in the pamphlet) at present from small-pox cultivated through a series of calves, has the same visible results—viz., a local eruption never communicated except by inoculation. 2. It is further stated that "the assumption that vaccination mitigates small-pox is absurd in theory and untrue in fact, for no one can possibly tell theoretically whether vaccinated persons who contract small-pox would have suffered more or less severely had they not been vaccinated." In any given instance that is true; but when it is found by comparison that the cases of severe small-pox occurring in vaccinated persons form a negligible fraction per hundreds of thousands of vaccinations, while the cases of severe small-pox in unvaccinated persons have a heavy percentage, it is only a reasonable assumption based on the doctrine of chances that the vaccinated patient would have suffered more severely if he had not been vaccinated. 3. Not vaccination but improved sanitation, we are told, is responsible for the improvement in small-pox incidence and mortality. Now, in the nature of things it takes time to convert insanitary conditions into sanitary ones, while the beneficial effect of vaccination, if any, we should expect to demonstrate itself promptly. When Porto Rico came under United States occupation in 1898 small-pox was endemic there and sanitation was not good. In December, 1898, small-pox assumed such a severe epidemic form in that island that 16 out of 71 municipalities showed 3000 cases in two months. On Jan. 27th, 1899, it was ordained that "every resident who has not had this disease will be vaccinated, and hereafter all infants must be vaccinated before reaching the age of six months." By June 30th, 1899, 790,000 persons had been vaccinated, not a death attributable to vaccination had occurred, and the only accidents were "a few infected arms." On Oct. 20th, 1899, it was officially reported that "not a single case of small-pox is known to either the military or the civil authorities, and it may be considered stamped out of Porto Rico." It has never gained a foothold there since. A similar, but if anything more remarkable, experience was afforded a year or two later in the Philippines.

THE DREAM OF ANTHROPOLOGY.

It has always been a dream of the anthropologist—a dream the realisation of which would prove one of the romances of science—that from an examination of the skull it should be possible for one versed in the study to reconstruct faithfully the features which characterised the individual the bones of whose head and face are preserved. The fascination of such an ideal is so great that it must strike anyone as curious that those whose business it is to handle skulls have been contented with stereotyped measurements and indices which seem to tell so little about the living individual. As a matter of fact, these seemingly sterile methods do not represent the true limits of anthropology, for it is certain that in the review of any skull the anthropologist sees far more of the living man than the mere collection of measurements and indices, with which he is forced to describe it, would suggest. The truth is that every anthropologist has his dreams; that some portion of his dreams he can realise, but that for want of a better method of expressing himself he resorts to the compilation of tables and indices, with which he is probably by no means contented. What he has seen in the skull is, alas, not represented in his tables, and no one who chances to wade through his records can ever build again that picture of the living individual or even of the skull from which it arose. Gropings after graphic methods are always being made, methods by which, at any rate, a skull contour may be reconstructed from data recorded by the observer; but more than this is wanted to fulfil the dream of anthropology, for a reconstruction of the actual features of the living individual is the climax aimed at. From time to time the question has attracted attention from a wider circle than that of the professed anthropologists, for the skulls reputed to belong to various great men have at times come under examination for the purpose of deciding either their authenticity or the fidelity of disputed portraits said to depict the living man. The skull said to be that of Dante was examined in 1867 by Welcker, and from its general similarity to the poet's death-mask it was judged to be genuine. The death-masks, the portraits, and the reputed skull of Schiller have also furnished material for an exhaustive study by the same authority. Raphael and Bach have in their turn provided problems for the anthropologist. Sophocles has also come under review, for a skull reputed to be his was examined by Professor His in 1893. The remains of other celebrities have been brought to light and paraded before the public from time to time. The disputed head of Cromwell attracted attention not long ago, and suggestions have been made of late

that the famous curse should be braved, and Shakespeare's remains be dragged from the grave in order to determine which of his portraits is genuine. Authorities differ as to the extent to which reliance may be placed upon the verdict that a particular skull accords so well with a particular portrait that therefore the bones must be actually those of the individual depicted. Still more doubt has been cast upon the value of attempts to reverse the process and reconstruct the portrait from the skull. So much that lends every distinctive feature to a face would seem to leave no trace upon the contours of the skull bones. The eyes, the lips, the nose have in all their most characteristic parts so little connexion with the bones that it is too much to expect that a faithful likeness could be reproduced. And yet something may be done. The artist's reconstruction of the features of an Australian native upon a skull handed to him by Merkel gives clear evidence that broad racial characters may be brought out with some distinctness upon a face modelled from the skull. It is possible that something more than this may be arrived at by a long series of comparisons of the features of actual individuals with the characters of their skulls, and by a systematic study of the average thickness of the tissues overlying every part of the skull bones. An excellent contribution towards this study has recently been made by Professor H. von Eggeling ("Physiognomie und Schädel"), and in his paper the writer gives a valuable account of what has so far been accomplished and what may yet be done. Professor von Eggeling has done his best to realise the dream of anthropology.

KALA-AZAR AND THE BED-BUG.

That certain human diseases are spread through the instrumentality of biting insects has been proved over and over again, and the number of such instances is gradually increasing. The latest addition to the list would appear to be the association of the bed-bug with the propagation of kala-azar (black fever) in India. In THE LANCET of Feb. 17th we briefly referred to the announcement which Surgeon-General W. B. Bannerman, I.M.S., has made to Sir Ronald Ross, that Captain W. S. Patton, I.M.S., had discovered the complete development of the parasite of kala-azar in the Indian and European bed-bugs. As the form of this disease met with in India is the most serious of the three known forms of illness due to Leishmania, it is obvious that the discovery of the life-cycle of the protozoal parasite in an insect which infests many Indian homes will clear away at once much of the doubt and difficulty which have hitherto surrounded our knowledge of the precise manner in which the disease is spread, and how it may therefore be prevented. For some time the Indian bed-bug has been under suspicion as the transmitting agent, but no sufficient evidence had been obtained to establish the charge. Captain Patton, now assistant director of the King Institute, Madras, sharing the views held by Major L. Rogers, I.M.S., who has already done much solid work towards the elucidation of the etiology of this disease, has been directing his investigations to the connexion between the bed-bug and kala-azar. He had already shown [1] that the parasite's life-cycle consisted of three stages —pre-flagellate, flagellate, and post-flagellate. The flagellate stage was said to be found in the mid gut of the Indian bed-bug, Cimex rotundatus, and the post-flagellate in the rectum, where the parasites became encysted and were finally passed out with the fæces, being liable, it was conjectured, to be ingested by the larvæ or nymphs. But it may be mentioned that Sir Patrick Manson has pointed out that the supposition that the infection took place by an animal feeding on the excreta of its own species was contrary to the usual course of nature. It was also believed that the parasite, in order to reach man, must revert to its non-flagellate stage, and that this change most likely took place in the bed-bug somewhere in the neighbourhood of its biting apparatus. It had been shown experimentally by Captain Patton that the Indian bed-bug could become infected by feeding on the blood of a kala-azar patient. But the final stages of the development of the parasite and the method of its re-entry into the human body could not be determined. The difficulties connected with proof of the insect transmission of flagellated protozoal organisms are notorious, and experimental research in this direction is acknowledged by experts as being far from easy. The natural parasites of the suspected insect, for example, would need careful study, and there might be difficulty in determining whether any parasites found in the bug were developmental forms of leishmania or were, on the other hand, flagellates of another kind altogether. It is therefore the more satisfactory now to learn that in spite of all the great difficulties which had to be encountered Captain Patton has succeeded at last in discovering the complete life-cycle of leishmania donovani in the body of the bed-bug. We assume that this discovery brings with it the knowledge that the bug is not only a potential agent, but that it is the usual transmitter of the infection to man. The practical application of this knowledge to the formulation of preventive measures naturally follows. Indeed, this view has already been acted upon with advantage in some parts of India, bug-infested huts in which cases of kala-azar had been reported having been destroyed by burning, and the human inmates removed to new homes erected on fresh sites. This incrimination of the bed-bug by Captain Patton affords another instance of the importance of cleanliness in dwellings, and the need for waging constant warfare against biting insects, more particularly on those which rely upon man for their sustenance. As we have before pointed out in these columns, it cannot be too often urged that the prevention of many diseases depends primarily upon the condition of the home, and that cleanliness of interiors avails much in the struggle against infection. We shall look forward with much interest to seeing the full details of Captain Patton's important investigations, and we trust that their publication will not long be delayed.

THE DIETARY OF THE ELIZABETHANS.

A LITTLE-KNOWN work is Thomas Moffet's "Health's Improvement," which deals with the choice and preparation of food in Elizabethan England. It is just to note that our ancestors, often accounted gluttons, held nice views on the subject of diet, ate many viands now discarded, and based their opinions of their bill of fare on the writings of Galen, Cardanus, and like authorities. The Elizabethan ate his meat in an eclectic and philosophic spirit. "I affirm with Galen," exclaims Moffet, "that a fat and young heifer, kept up a while with dry meat, will prove a convenient, temperate, and good nourishment, especially if it be killed after the French fashion, as I saw the Norman butchers kill them in our camp whilst I lay there in camp with that flower of chivalry, the Earl of Essex." The Normans, it appears, inflated the carcass of the cow with wind and then beat it till the meat grew tender, as is now done in the case of veal. Bull beef is said by this same writer to be a fit food for strong stomachs, but only after the bull has been baited and has died in battle. "Mutton is generally commended of all physicians." The flesh of the old he-goat is not to be eaten "till he hath been baited like a bull to death, and when he is dead, you must beat the flesh in the skin after the French fashion of beating a cow." "No brawn,

pork, or bacon should be eaten without wine." A certain prejudice seems to have existed against the flesh of red and fallow deer as being too dry and cold. In that age of humoralistic medical theory all food is, indeed, judged according to a fictitious standard. Some meats are held to be heating, others are watery, and the choleric must not eat of the former or the weakly of the latter kind. The list of birds that came to table in the days of Shakespeare is enough to stagger the Wild Birds Preservation Society. Thus, robin redbreasts are esteemed "a light and good meat," and all the little song-birds are mentioned as edible. The jay has a bad name. He suffers from falling sickness and conveys it to others. The sparrow has an aphrodisiac effect; the wag-tail is conducive to the shaking palsy; the wren is hostile to stranguary and the stone; the cuckoo is "hot and leprous." Fishes, especially the fresh-water kinds, are recommended on much the same grounds as birds. Loches are good for women in childbed; the liver of the whale is said to smell like violets and to taste most pleasantly. Lampreys are very sweet and nourishing, but they tempt men to surfeit. "How ill they are even for strong stomachs, and how easily a man may surfeit on them, not only the death of King Henry I. but also of many brave men and captains, may sufficiently demonstrate." Caviare, under the name of cavialy, is praised, but an Italian proverb is quoted—

> "Chi mangia di Caviale
> Mangia moschi, merdi, e sale.

This is not civil. It is curious that the taste for caviare survives while that for lampreys has disappeared. Dr. Thomas Moffet was a fine specimen of the physician of his age. A person of many accomplishments, a courtier, and traveller, he ranks as one of the worthies of Caius College and Trinity College, Cambridge. His curious book retained such influence that it was reprinted as a serious contribution to knowledge as lately as 1746.

ARTIFICIAL HYPOSPADIAS FOR INTRACTABLE URETHRAL STRICTURE.

IN the *Australian Medical Journal* of Dec. 23rd, 1911, Mr. R. Hamilton Russell has described an ingenious operation for the relief of intractable urethral stricture. He conceived the project of producing artificial hypospadias and subsequently operating for its relief, making a new urethra independent of the stricture. A man, aged 44 years, was admitted to hospital with complete retention of urine accompanied by uræmic symptoms. Some four years previously he had undergone perineal section, but had gone up the country, with the result that his urethra was neglected. Artificial hypospadias was performed, and so great was the relief and so inconsiderable the inconvenience involved that he declined any further operation. The procedure is very simple. The scrotum is first divided longitudinally throughout along the median raphé until the corpus spongiosum is exposed. The opening will be diamond-shaped when the testes are drawn to either side. Each half of the scrotum is sewn up with horsehair applied antero-posteriorly, commencing at the outer angles of the diamond and continued inwards towards the middle line as far as convenient, so that each testis is sewn up in a separate bag. A director is now passed into the urethra, which is opened a little in front of the scrotum. The urethal incision is carried backwards into the perineum past the strictured portion. The whole length of the incised urethra is stitched on either side to the skin, whether of the penis, scrotum, or perineum. In this way a condition closely simulating perineo-scrotal hypospadias is produced, the differences being that the anterior portion of the urethra is not laid open and the penis and glans are mobile and free. The operation is completed by tying in a rubber catheter through the perineal wound and applying a simple dressing of gauze and wool. The scrotal sutures should not be removed for 10 days. In a second case a man, aged 80 years, had suffered from intractable stricture for 40 years. One day he suddenly became comatose and his medical attendant aspirated the distended bladder as he could not pass a catheter. After 12 hours consciousness returned. Next an attempt to pass the stricture under chloroform failed. The membranous urethra was opened through the perineum and a rubber catheter passed into the bladder (Cock's operation). Several ounces of very foul urine and pus were evacuated and the bladder irrigated. A week later the operation described above was performed, with the result that the trouble which had rendered life a burden for 40 years was removed. Washing out the bladder was then a simple matter. At first it would not tolerate more than 4 ounces of urine, but within a fortnight it could take 18 ounces comfortably. The drawbacks to the operation are loss of procreative power and having to perform micturition in the feminine fashion. Neither of these is serious in men who have reached or passed middle age. They are trivial in comparison with the troubles relieved. Sexual power would doubtless be unimpaired. It might be suggested that the making of a permanent urethral fistula would do equally well without dividing so much of the urethra, but Mr. Russell does not think so, and believes that the division of the scrotum adds greatly to the comfort and facility with which micturition can be performed. He also suggests that in traumatic stricture involving the membranous urethra the operation may be useful. Although it would not be possible to get behind the stricture, the difficulty in managing it experienced through the urethra would be much diminished in dealing with it at close quarters through the perineum.

THE MINERAL WATERS OF ESSEX.

AN interesting contribution has been added to the Essex Field Club Memoirs in the form of a history of the mineral waters and medicinal springs of that county by Mr. Miller Christy, F.L.S., and Miss May Thresh. It appears that in Essex there are a considerable number of springs which have been in the past valued for medicinal purposes and visited more or less extensively by persons who regarded these waters to have curative properties. Altogether, we gather, rather more than a score of such wells attained at one time a certain measure of fame. The well at Wanstead became known at the very beginning of the seventeenth century. Some eight others—Witham, South Weald, Upminster, Little Leighs, Felstead or Little Dunmow, Mark's Hall, Woodham Ferrers, and Colchester—were known and used at least as early as the end of the seventeenth century. About a dozen others (namely, those at Woodford, West Tilbury, Havering, Chigwell Row, Wethersfield, Gidea Hall, Hornchurch, Stapleford Abbotts, Springfield, Twinstead, Plaistow, and Ilford) appear to have been discovered during the eighteenth century, while only two—Hockley and Dovercourt—became known during the nineteenth century. The wells containing an important quantity of salines were at South Weald and Upminster, which provided chiefly the sulphates of magnesium, calcium, and sodium; Hockley water was a bitter magnesium water. The rest appear to have attracted attention through their chalybeate properties. At Dovercourt an attempt was made to establish a regular spa about 50 years ago, and a spa-house exists there to-day. At Hockley a spa was established and a pump-room built in 1842, but the enterprise failed, for in 1871 it was written that the whole place had "a most dilapidated appearance, the hotel has been let at £10 per annum as a beer-shop, and the unfortunate spa-room is used as a Baptist chapel." In

1893 another attempt was made to develop the spa, but without success, until two or three years ago a builder took the matter in hand, with the result that "the Spa Hotel (a couple of hundred yards distant from the pump and well) on the road from Rayleigh to Rochford, after many years of decadence, is at last a prosperous hostelry, and it is likely to do well now that the exceptionally picturesque district around Hockley is developing rapidly as a residential district." The water contains as its chief constituents, according to Miss Thresh, 197·3 parts per 100,000 of magnesium sulphate, 95·9 parts of calcium sulphate, 95 parts of sodium chloride, and 39·7 parts of calcium carbonate. It acts as a gentle aperient, and shows a composition which, if the spring had been on the continent, would have attracted a *clientèle* long ago.

ACUTE DILATATION OF THE STOMACH IN PNEUMONIA.

ACUTE dilatation of the stomach is a rare condition which has attracted increased attention in recent years. Upwards of 200 cases have now been recorded. Its pathogenesis is somewhat obscure. It may occur without obvious cause in an apparently healthy person, in the course of some disease, or after some operation, abdominal or not. In the text-books it is stated to occur sometimes in severe acute or wasting diseases, but it does not appear to be mentioned among the complications of pneumonia. Yet ten years ago in our columns Dr. H. Campbell Thomson published an important paper on acute dilatation of the stomach, in which he reported one case in which it occurred in pneumonia,[1] and Dr. Charles R. Box and Mr. Cuthbert S. Wallace reported a second case.[2] A paper in the *American Journal of Medical Sciences* for December, 1911, by Professor M. H. Fussell tends to show that acute dilatation of the stomach is not such a rare complication of pneumonia as might be supposed. The connexion first attracted his attention in July, 1910, since which date he has seen three other cases, and on searching his notes he found a fifth case, observed in 1904, in which the connexion with pneumonia was not recognised at the time. The following are some examples. A youth, aged 20 years, was attacked with severe pneumonia involving first the right lung and then the left until only the right upper lobe appeared to be in use, though there was some resolution at the right base. The temperature ranged between 103° and 104° F. The pulse was very rapid, frequently reaching 140. Resolution slowly progressed and the temperature fell by lysis. Three days after the temperature had been normal much creamy sour material was suddenly vomited. Professor Fussell saw the patient a few hours later and found the stomach greatly distended. The left hypochondriac and umbilical regions protruded while the right hypochondrium was flat. The outline of the stomach could be seen, and tympany extended almost to the pelvis. The patient was collapsed and the pulse running. Notwithstanding his apparently moribund condition a stomach tube was passed, much liquid was removed, and the stomach was washed out. The protrusion immediately disappeared and the patient was much relieved. Recovery ensued. In a second case the pneumonia was confined to the left lower lobe in a man aged 35 years. On the fourth day the temperature suddenly fell to normal, but it again rose to 102°, and on the sixth day there were symptoms of intestinal obstruction. The abdomen was greatly distended and the bowels could not be got to act by any means. On the seventh day Professor Fussell saw him in consultation and found that the abdominal distension was epigastric and extended 2 inches below the umbilicus, forming a tympanitic tumour. The pulse was rapid, but good. There was complete consolidation of the lower left lobe, which was undergoing resolution. The patient was semi-comatose and delirious, and there was some vomiting. A stomach-tube was introduced and a small amount of sour material was obtained, with much gas. The epigastric tumour immediately disappeared and the abdomen became flaccid. On the next day and on three other occasions the stomach was washed out, and after the fourth washing there was no return of the distension. Eserine and strychnine were given hypodermically and recovery ensued. Professor Fussell has collected from literature six other cases. Analysis of the whole 11 cases shows that 6 were fatal. The dilatation occurred before the crisis in 8, after it in 3. Collapse is reported in 5, diarrhœa in 2, and vomiting in 8. Most of the patients were delirious. In two cases the vomit had a fæcal odour. Constipation was the rule. Frequently the patient was collapsed, with pinched anxious face, sunken eyes, and rapid breathing. The condition must be differentiated from general intestinal distension, peritonitis, and intestinal obstruction. General abdominal distension is common in pneumonia, but the outline of the stomach cannot be made out, the stomach tube will not remove the distension, and frequently a rectal injection will give relief. Moreover, there is no vomiting, and often there is diarrhœa. In general peritonitis there is the same rapid distension as in gastric dilatation, but the outline of the stomach cannot be seen, and the abdomen is tender. In three cases intestinal obstruction was diagnosed. But in it the distension is general, and the passage of the stomach tube will not cause this to disappear. Sudden abdominal distension in pneumonia should suggest acute gastric dilatation. Before the patient is moribund the stomach tube should be passed and lavage performed. This must be repeated as often as the dilatation recurs. The position of the patient is of some importance. If, as is held by some, the cause of the dilatation is constriction of the duodenum under the root of the mesentery, this may be removed by turning the patient on the right side or on the face. Professor Fussell thinks that these pneumonic cases are in favour of some toxic cause affecting the innervation of the stomach. The dilatation so caused may, by traction, produce constriction of the duodenum.

SOME DEVELOPMENTS IN PHARMACEUTICAL RESEARCH.

IN the domain of pharmaceutical research some useful work has been accomplished since the beginning of the present year, evidence of which is to be found in the three papers that were communicated to the February evening meeting of the Pharmaceutical Society in London. In the Pharmacy Research Laboratory of the society Professor H. G. Greenish, joint editor of the forthcoming edition of the British Pharmacopœia, is, with the assistance of Miss D. J. Bartlett, undertaking a series of experiments with the object of drawing the attention of pharmacists to drugs the sophistication of which exists in more than isolated cases. The first report on these investigations deals with powdered gentian, nux vomica, and ipecacuanha, and was the subject of one of the communications in question. Of powdered gentian 33 samples were examined, and 13 failed to comply with the requirements of the Austrian Pharmacopœia as to aqueous extract. The yield of aqueous extract depends not only on the original quality of the root, but also on the treatment to which the root has been subjected, and the test serves to exclude exhausted root, while it excludes definitely highly fermented root. The 13 samples were therefore of poor quality. On the other hand, with five exceptions, the samples

satisfied the ash-limit of the Austrian Pharmacopœia. An examination under the microscope showed that five samples were grossly adulterated, three of them containing an abundance of almond shell; five others also showed evidence of contamination with foreign vegetable substances, and the authors draw the conclusion that "the quality of commercial powdered gentian still leaves much to be desired. Intentional adulteration with foreign vegetable powders still continues. Carelessly cleaned root is ground to powder, and a large proportion of the samples are deficient in water soluble substances." The 11 samples of nux vomica examined gave much more satisfactory results, and the 11 samples of powdered ipecacuanha, with one exception, contained sufficient total alkaloid to comply with the requirements of the Committee of Reference in Pharmacy. The series of investigations promises useful results, and if other drugs are found to be adulterated to the same extent as powdered gentian root valuable caution will be instilled. In another paper read at the same meeting the same authors demonstrated that the frequently repeated statement that black mustard seeds do not always contain sufficient myrosin to decompose all the sinigrin they contain, was incorrect. In two of the samples of black mustard seeds examined there was, in fact, sufficient of the enzyme to decompose a much larger quantity of the glucoside than the seeds themselves contain, while in all the samples there was a sufficiency of myrosin. It therefore follows that the practice of adding white mustard seeds, which contain an excess of the same or a similar enzyme, myrosin, is not necessary to complete the decomposition of the glucoside, although a mixture of the two kinds of seeds may be more palatable than the black seed alone. The third paper consisted of a preliminary report on examinations of asafœtida and oil of asafœtida which have been conducted by Mr. E. F. Harrison and Mr. P. A. W. Self. The authors describe in detail the process employed in investigating the oil, and, since there is good reason to believe that the virtues of asafœtida are chiefly due not merely to the essential oil but to the sulphur-containing constituents of the oil, they draw especial attention to the importance of an accurate determination of the amount of sulphur present. They showed that high percentage of sulphur in the oil goes with high specific gravity, high refractive index, and levorotation, while the lowest percentage of sulphur goes with the lowest specific gravity and refractive index, and dextrorotation. The authors were reluctant to suggest that the figures they obtained established any sort of standard or limit, although the samples were chosen to be as representative as possible; they are inclined to think, however, that when the amount of sulphur in the oil is not under 1·5 per cent. of the real gum resin, there is a *primâ facie* case for regarding the drug as pure. They are continuing their investigations in the hope that the accumulation of further data may lead to results of greater value.

THE PATHOLOGY AND TREATMENT OF TUBERCULOSIS.

IN another column we publish a communication from our correspondent at Budapest with regard to the views held by Dr. Joseph Hollós respecting certain points in the pathology and treatment of tuberculosis. The remarks on latent and masked tuberculosis will doubtless be received with a considerable amount of scepticism by practitioners in this country. Nevertheless we have thought it well to publish them, as they have received some attention from French observers. Certain symptoms are detailed which Dr. Hollós believes are indicative of latent tuberculosis, but similar symptoms occur in so many other conditions that much hesitation will be experienced in accepting Dr. Hollós's contentions that they are due to the "high quality of sensitivity" of the organism against the toxins of tuberculosis. Dr. Hollós also states that patients in the latent stage of tuberculosis respond well to antituberculous treatment. The patients under his care were without exception treated with Spengler's serums—namely, the smaller proportion of them with tuberculin and the larger proportion with the "tuberkulose Immun-Körper" (I.K.). In THE LANCET of Sept. 16th, 1911 (page 838), we made some remarks on this "I.K." treatment for tuberculosis, and after a criticism of the accounts which had been published claiming very favourable results from the employment of the preparation we asked our readers to receive the results of employing "I.K." with reserve for the present. After reading Dr. Hollós's remarks our opinion is not changed, but we should be interested to receive from our readers any personal experience they may have had in treating patients with Dr. Spengler's serums.

THE CANADIAN ROYAL COMMISSION ON TUBERCULOSIS.

WITH the administration of sanatorium benefit under the National Insurance Act in view, the attention of statesmen, Insurance Commissioners, local authorities, and practitioners may be directed advantageously to the report of the Royal Commission on Tuberculosis for the Province of Quebec recently issued. The report presents the problem of the prevention and eradication of tuberculosis in clear, concise, and eminently practical fashion. For ready reference the arrangement of the report is excellent. The body of the report is prefaced by a short summary of six pages which contains the more important conclusions. Following this comes the detailed report with excerpts from the evidence. The Commission consisted of 14 members, and included Dr. E. P. Lachapelle (chairman), Professor J. G. Adami, Dr. Roddick, and Colonel Jeffrey Burland, the donor of the Royal Edward Institute. The general conclusions include an emphatic statement that tuberculosis is infectious and transmissible. The unavoidable confession is made that the mortality from tuberculosis is higher in the Province of Quebec than in the Province of Ontario and the adjacent United States. It is further pointed out that the death-rate from tuberculosis in the rural population equals that in the urban population, who, theoretically, live under more unhealthy conditions; that the mortality among women is considerably greater than among men; and that the mortality among French Canadians is higher than among Anglo-Canadians. Attention is especially drawn to the spread of tuberculosis through contagion in families, in the collective life of schools, boarding schools, offices, and workshops—in short, through the influence of vitiated air in all places where people are gathered together. Means for combating tuberculosis are divided in the report broadly into: (1) Measures that can be carried out at once; and (2) measures to be carried out gradually. Among measures which the Commissioners hold can be carried out at once are included stricter application of the laws contained in public health statutes, the teaching of hygiene in schools, popular education in relation to tuberculosis, the medical inspection of schools and industrial establishments, the establishment of tuberculosis dispensaries in the principal centres, the erection of isolation hospitals for advanced cases among the poor, the establishment of open-air schools for certain groups of children, and legislative measures regarding institution of farm colonies and holiday colonies, the the employment of children, the abuse of alcoholism, and the inspection of meat and milk. Among measures to be carried out gradually may be noted the creation of sanatoriums, the improvement of dwellings under existing statutes, and fresh legislation to promote the building of cheap, healthy

dwellings for the working classes, and the improvement of hygiene generally throughout the province. Finally, the report terminates by the submission to the Lieutenant-Governor in Council of certain recommendations relating especially to the share the Government should take in the campaign against tuberculosis. These include the following five most practical requests, of which, in view of their significance in the present issue before the country, we reproduce the *ipsissima verba*.

1. That very explicit instructions be given to the Provincial Board of Health, to municipalities and other duly constituted authorities to enforce the regulations respecting the compulsory notification of tuberculosis, the disinfection of contaminated premises, the healthy condition of dwellings, schools, and industrial establishments; and that such authorities be actively assisted by the law officers when compelled to enforce such regulations.

2. That the Provincial Board of Health be the central authority which will direct the application of the means of combating tuberculosis and, to that end, that it be given a sufficient appropriation to establish a special department for tuberculosis with the necessary staff. That department should be under the direction of a *physician of acknowledged competence in the matter* (the italics are the Commissioners') who would apply all the educational means mentioned in the report, inspect the antituberculosis institutions, and strive to have others established to complete the antituberculosis armament, compile statistics, and submit a yearly report on his administration and on the results of the campaign against tuberculosis.

3. That in every municipality or union of municipalities, where there is a chartered antituberculosis association, the Government, on a favourable report of the Provincial Board of Health, contribute a proportionate amount (to be determined) towards the cost and maintenance of every established dispensary and empower the municipalities served by such dispensaries to contribute an equal amount towards their erection and maintenance.

4. That the Government contribute a proportionate amount (to be determined) towards the establishment of isolation hospitals or the construction of special pavilions in existing hospitals receiving advanced cases of tuberculosis among the poor and empower the municipalities served by such isolation hospitals or pavilions, to contribute to their erection and maintenance.

5. That the Government contribute a certain amount (to be determined) towards the maintenance of advanced cases of tuberculosis among the poor, in special hospitals or pavilions, by distributing that amount *pro rata* at so much per head and per week, and empower municipalities to also contribute in the same manner to the same object.

The recommendations are based on most interesting evidence which is cited throughout the body of the report and on the plan of the antituberculosis campaign of the city of New York and the plan of the antituberculosis campaign in Edinburgh, an account of each of which is included in valuable appendixes, which contain also an account of the present condition of the campaign against tuberculosis in the various provinces of the Dominion of Canada.

Dr. Archibald E. Garrod, F.R.S, has been elected physician to St. Bartholomew's Hospital to fill the vacancy caused by the retirement of Dr. Norman Moore from the active staff of the hospital.

HUNTERIAN SOCIETY.—The 93rd anniversary dinner of this society was held at De Keyser's Royal Hotel on Feb. 7th, the President, Dr. R. Hingston Fox, being in the chair. There was an attendance of 66 Fellows and guests, including ladies. The Royal toasts were proposed by the President; "The Hunterian Society" was proposed by Sir George Newman and replied to by Dr. A. T. Davies. "The Guests" and "Sister Societies" were proposed by the President. Mr. Rickman J Godlee replied for the Royal College of Surgeons of England, and Dr. J. Mitchell Bruce for the Medical Society. Dr. T. B. Hyslop spoke for the guests. A programme of music was provided by Miss Christine Roy and Mr. Robert Carr, vocalists, and Mrs. A. C. Jordan, who gave violin solos, Miss Gwendoline Williams playing the accompaniments. The music was much appreciated. The annual oration was delivered at the London Institution on Feb. 14th by Dr. T. Glover Lyon on "The Cure of Consumptives, a Review and a Forecast." Dr. Lyon emphasised the important part played and to be played by sanatoria in the treatment of consumptives, and drew attention to many practical points in which sanatorium treatment, as conducted in most existing institutions, failed to conform to the needs of the various types of patient.

AN EXAMINATION OF THE MEDICAL PROVISIONS OF THE NATIONAL INSURANCE ACT.

BY WILLIAM A. BREND, M.A. CAMB., M.B., B.SC LOND,
OF THE INNER TEMPLE, BARRISTER-AT-LAW; LECTURER ON FORENSIC MEDICINE, CHARING CROSS HOSPITAL.

III.[1]

Estimates of Attendance Required.

UNTIL the regulations are issued by the Commissioners, uncertainty must exist as to the services which are to be performed by practitioners under medical benefit. Nevertheless, attempts have been made to estimate the number of attendances which, on the average, each insured person will require, from the attendances received at present by members of Friendly Societies and clubs, including visits to patient's houses and consultations at home. It is worth while examining how far these figures are applicable to the persons who will be insured. The British Medical Association is collecting exact information on the point, but pending its publication the following may be quoted:—

Reference.	Number in club.	Average attendances.	Remarks.
B.M.A. Contract Practice Report, p. 14.	40,893	4·1	Figures totalled from 269 clubs.
Letter, *B.M.J.*, May 27th, 1911 (figures for 10 clubs)—			
Club B	42	2·8	Resident staff of firm—young men.
,, D, E, F, & G ...	267	4·5	Oddfellows.
,, H	41	1	Visits exceptionally distant.
,, I & J	229	5·8	Include single employed women.
,, K	195	3·8	—
,, L	15	3·2	All clerks.
From "Thirty Years Provident Dispensary Work," 1911.	Several thousand.	4·77	Unselected lives; no age-limit; 78% women and children.
Market Drayton Dispensary, *B.M.J.*, Dec. 2nd, 1911.	810	6·5	Unselected lives; bulk women and children.

Scattered through the Contract Practice Report, and in the columns of the medical journals for the last year, will be found other figures and estimates of a similar character. Most of them range between 1 and 6. The average for clubs consisting of adults examined before admission and with an age-limit appears to be about 4.

In applying these figures to the insured population the following factors have to be considered.

Value of life.—In most clubs there is an examination for admission, though often not of a very rigid character. Members of approved societies, despite the arrangements for deposit contributors, are not likely to be highly selected. Indeed, several important societies have already announced their intention of accepting members without any medical examination at all. But, as pointed out, promise has been given that bad lives shall be treated at a special rate of remuneration, and it is within the power of the Insurance Commissioners to arrange for a medical examination in every case before requiring a person to be attended at the ordinary fee. Thus that part of the insured population treated at the general rate might be more selected than existing club members.

Sex constitution.—This is of importance in view of the fact that women are believed to require more medical attendance than men. The actuaries estimate the number of persons likely to become members of approved societies, excluding Ireland, at: men, 8,530,000; women, 3,522,000—i.e., 70 per cent. men. These figures were compiled before the right was given to employed married women who were insured before marriage to continue, if they so elect, to be insured

[1] Articles I. and II. were published in THE LANCET of Feb. 10th (p. 383) and 17th (p. 447).

after marriage upon a reduced scale of benefits and contributions. The number who will exercise this right cannot be determined, but the actuaries suggest that it might be 700,000 in the course of ten years. Attendance in cases of maternity is of course excluded from medical benefit.

Age constitution.—The following is given by the actuaries as the probable age-distribution of persons expected to become members of approved societies:—

Age.	Number.	Age.	Number.
16–20 years	2,004,000	40–50 years	1,969,000
20–30 ,, ...	3,826,000	50–60 ,, ...	1,179,000
30–40 ,, ...	2,733,000	60–65 ,, ...	341,000

It will be noticed that 71 per cent. are under 40 years of age. In existing clubs the average age is probably higher. Sir Thomas Whittaker, during the debate on the second reading of the Bill, said that the position of some of the Friendly Societies was precarious and actuarially unsound owing to the increase in the number of the older members. "One of the strongest societies, the Hearts of Oak, has now three times as many members over 70 years of age as it had ten years ago."

Effect of sanatorium benefit.—If arrangements are made whereby advanced and chronic cases of tuberculosis can be sent to appropriate institutions, an appreciable reduction of the work required from the general practitioner may be anticipated. It has been estimated that 25 per cent. of the sick pay of the Foresters is in respect of this malady.

Venereal disease.—In practically all clubs this is an "extra." Under the Act it will be treated as part of medical benefit.

Organisation of the profession.—Advantage may be anticipated from the fact that in place of the existing competition, which has led to such disastrous results, medical men will be working together upon panels and in committees. This will enable arrangements to be made for mutual benefit. For example, medical men might agree to exchange patients, subject to their consent, so that each practitioner would have the bulk of his work in his immediate neighbourhood. It is said that insured persons will make unreasonable demands for medical attendance. There does not seem to be any cause why such abuse should be greater than it is among existing club patients, but in any case the profession will be in a stronger position to deal with it under the Act. Where at present a practitioner hesitates to complain of a tiresome person for fear of losing an appointment, he will in future run only the risk of losing a single patient. It is said, too, that attendances among club patients are swollen by malingering. But if the Medical Committees are given power to deal firmly with this evil, it should under the Act be reduced to a minimum. In comparing existing with future conditions it should be borne in mind that, except in localities where special arrangements are made, time will not be occupied in dispensing. It would appear, therefore, that several factors make, or may make, for a reduction in attendance as compared with that now given to members of clubs. If a reliable estimate could be made of the number of attendances each insured person, on the average, is likely to require, a useful step preliminary to fixing an adequate fee would have been taken.

The Remuneration.

Payments will be made to practitioners for medical attendance and treatment by the Insurance Committees with which they contract. The revenue of the Insurance Committees out of which the cost of medical benefit will be paid is to be derived partly from approved societies, which by Section 15 (6) are required to pay to the Insurance Committees such a sum in respect of their members as may be agreed upon between the society and committee, or in default of agreement may be determined by the Insurance Commissioners. No specific sum is mentioned here or elsewhere in the Act; the matter is entirely one for local arrangement or determination by the Commissioners. The remainder will be paid, in respect of deposit contributors, under Section 42, which provides that there shall be paid each year to the Insurance Committee out of the Post Office fund such sum as the Insurance Committee, with the consent of the Insurance Commissioners, determine. Here again no amount is specified by the Statute.

The 6*s.* which has been so often referred to was the sum the actuaries were told to assume as the cost of medical treatment and medicines for the purpose of determining the Government contribution. Whilst it is in no way statutory, it is probable that it will form a basis from which to start negotiations. In the ensuing paragraphs it is spoken of only in that sense.

To determine how the Insurance Act is going to affect medical practitioners financially is really a very difficult matter. Many doctors have stated that they anticipate losing from one-fifth to one-half of their income, but facts and figures in support of these statements have not been abundant, and where given they have, in some cases at least, been based upon errors, instances of which have been quoted. The reason is that the full data required to make a comparison do not exist. It is only in respect of patients—that is, persons actually treated—that reliable figures are forthcoming. A practitioner can readily determine from his books the number of times he has seen each of his patients and the amount he has received per attendance. But what he requires to know in order to estimate his position in the future is the number of insured persons who will be on his books; persons for each of whom he will be paid, though some will not require medical attendance at all. It is impossible to see how this figure can be arrived at, except in rare isolated districts where there is only one practitioner, who can be looked upon as having practically the whole population of the district under his care. Nor is this the only difficulty. In determining who among his patients are likely to become insured, a medical man must not only be familiar with the qualifications and conditions laid down by the Act, but he ought also to possess certain private information regarding the incomes, ages, &c., of his patients, which in many cases he may not have. Finally, assumptions have to be made both as to the amount of the capitation or other fee which may be fixed, and the effect of any income-limit which may be imposed.

A rather more hopeful line of investigation is based upon an estimation of the total amount each practitioner will, on the average, receive from the fund for medical benefit. In round figures, the total number of persons who will eventually be insured for medical benefit is 13,000,000. The number of practitioners estimated to be available for service under the Act is 24,000.[2] On the average, then, each practitioner will have on his books 542 insured persons, in respect of whom there will be paid £162 for attendance and medicines. The total population of Great Britain is 40,834,714. Deducting 1,000,000 for persons in the services, &c., the number of persons to each practitioner is 1660. If, therefore, the whole population were insured at the same rate, the average medical income from medical benefit would be just under £500, out of which would have to be provided the cost of drugs, &c. It is, of course, impossible to determine what the average medical income is, but in a recent correspondence in the *British Medical Journal* it was placed appreciably below this figure.

Another rough comparison may be made by estimating as far as possible the total amount which is at present paid for medical attendance and medicines by the 13,000,000 persons who will be insured by the Act. It has been calculated that there are at the moment about 4,000,000 persons receiving medical treatment through Friendly Societies, of whom doubtless the great majority will become members of approved societies. Figures in the Contract Practice Report and elsewhere show that these pay on the average to the medical profession for attendance and medicines about 3*s.* 6*d.* per annum or, say, 4*s.* to allow for a certain number who, though subscribing to a club, pay a doctor privately. It may be taken that members of registered Friendly Societies on the whole do not consist of the poorest section of the working class. To quote the Contract Practice Report, "it is probable that the great bulk of the members of the registered Friendly Societies are, in fact, drawn from those of the working classes who follow regular occupations, together with a considerable number of small shopkeepers. ..... There is evidence that in various districts a considerable number of persons are taking advantage of the arrangements who are in a better social position than those for whom the service was intended." Do the remaining 9,000,000 pay on the average more or less than members of registered Friendly Societies? Of some of them the report says: "The smaller or unregistered Friendly Societies, and especially

[2] Brit. Med. Jour, Jan. 13th, 1912.

the Dividing Societies, while they provide mainly for a somewhat similar class, cater rather more than the large Permanent Societies for those who are less regularly employed." There is also a large class who subscribe to private clubs or provident dispensaries, and another large group who receive their medical attendance through the Poor-law or hospitals, or go without it altogether and resort to self-medication. An interesting light is thrown upon the expenditure by working girls on medical attendance, &c., by a volume published recently by the Board of Trade,[3] containing a detailed analysis of the total expenditure for a year of 32 girls employed in factories, dressmaking, and other occupations. The average weekly wage was 15*s.* 9*d.* Of the 32, one was insured for medical benefit. The total expenditure of the remainder under the heading of medical attendance and medicines was £12 5*s.* 5*d.*, and was made up as follows: medicines, £6 7*s.* 6½*d.*; dentist, £2 17*s.* 6*d.*; doctor, £1 5*s.*; miscellaneous, £1 15*s.* 4½*d.* The high proportion spent upon medicines is noteworthy. The bulk of it consisted of patent and proprietary drugs. "Miscellaneous" includes such expenses as payment of substitute while away from work, eye-glasses, chest-protector, &c. These were all young girls, but several were ill and away from work for various periods during the year. Still they must be regarded as to a certain extent picked, for any girl who was seriously ill would presumably not have been able to keep up the record.

Against these poorer classes must be placed the class of comparatively well-to-do private patients who may come in as voluntary contributors. Their numbers and qualifications have already been considered. While individually these will pay less, it does not seem probable that they will be so numerous as to wipe out all the gain upon the others.

These considerations have not been brought forward with a view of suggesting that a 6*s.* capitation fee is sufficient. No sum can be accepted or even considered by the profession until the duties to be performed for medical benefit have been defined. Under any circumstances an efficient service can only be obtained if the remuneration is adequate. It is merely intended here to point out the danger of making a claim for a higher fee on the ground that the profession as a whole is at the moment getting a larger total sum from the persons who will be insured than it will receive under the Act.

The method of payment is a matter for local arrangement. Payment by capitation fee has the advantage that it reduces the cost and trouble of bookkeeping.

Cost of drugs.—An obvious criticism of the foregoing is that the profession will not get 6*s.*, since this has also to cover the cost of drugs and such surgical appliances as may be prescribed. But for purposes of comparison it is necessary to take the higher figure, since medicines are usually included with attendance among the working class. It is currently assumed that the cost of drugs will be 1*s.* 6*d.*, leaving 4*s.* 6*d.* for the doctor. But there is no statutory authority for this division, nor is there anything to justify it in the Actuaries' Report. Most practitioners with knowledge of dispensing will agree that 25 per cent. is an unnecessarily high proportion to allocate to cost of drugs. It is a matter for regret that Insurance Committees are probably unable under the Act to open and conduct their own dispensaries, as the system by which an insured person can have a prescription made up by any chemist on the list is costly. Medical men themselves can help to reduce the expenditure. Probably there will be less drug-taking than there is at present, and medicines will be prescribed in more concentrated form and in larger quantities at a time. The indiscriminate sale of patent and proprietary medicines has always been regarded by the profession as harmful. The regulations might well require that doctors on the panel should be forbidden to prescribe them. As regards surgical appliances it is important to notice that Section 12 empowers a society or committee to provide them out of the fund for sickness benefit in the case of a person who is an inmate of any workhouse, hospital, asylum, convalescent home, or infirmary.

Payments from Other Sources.

It has been assumed by many practitioners that 6*s.* for medical benefit is the only sum that can be paid to them whatever the services they may be called upon to perform. Some, for example, have supposed that they will be required to furnish various reports and statistics under Section 60 which makes Insurance Committees responsible for such duties. But the Act clearly defines medical benefit as medical treatment and attendance, and practitioners will be justified in asking for additional remuneration for any services which are not of this nature. The point is of importance in view of the fact that the rate paid by the Government for attendance upon Post Office employees—viz., 8*s.* 6*d.*—is being used as an argument for raising the capitation fee for medical benefit to that figure. It must be remembered that for this remuneration Post Office doctors have to perform duties other than those of a purely therapeutic character. It is desirable to enumerate briefly the various services which may be the subject of extra remuneration from medical benefit, or may be paid for from other funds under the Insurance Act.

Extra medical services.—The guarantee that the profession has here is contained in the statement made by the Chancellor at the special Representative Meeting on May 31st. As reported by the *British Medical Journal*, June 3rd, he said: "Of course, the payment of a specialist would not be included in the capitation fee, and, therefore, if there were consultations, they must necessarily be outside the range of whatever capitation grant is paid; it must necessarily be. That would not be a burden cast upon the medical man, but the society, or the Local Health Committee, as the case may be, would have to pay that fee. With regard to operations, that also I should put in the same category. Most of the various operations—not all, of course—would be performed in institutions, and I can well understand the medical profession insisting upon special arrangements being made for serious operations. That is a matter you will have to arrange with the Local Health Committee, subject to the approval of the Insurance Commissioners." On the question of night work he did not express a definite opinion. The promise made on the same occasion of a higher rate of pay for bad lives has already been quoted. The Chancellor concluded with the remark, "I think it would be better for you if you were to confine yourselves to those three or four really big burdens upon the profession—consultations, operations, and mileage."

For major operations, arrangements will probably be made with hospitals, and Section 21 allows payments to be made to hospitals from various sources. It would obviously be unfair to charge to medical benefit the entire cost of an operation which has the effect of saving the funds for payment during sickness and disablement.

Mileage.—This might be regarded as covered by the promise that local circumstances shall be taken into consideration in fixing the capitation fee. Clearly 6*s.* is not high enough in a scattered country district, but is it quite reasonable to ask for a higher capitation fee and mileage in addition to that? In towns mutual arrangements between practitioners should reduce long journeys to a minimum.

Certificates.—It has already been pointed out that approved societies will require numerous certificates in order to make the payments in respect of sickness and disablement benefit. Medical practitioners will be under no contract with approved societies, and it will be a matter for mutual arrangement whether payment shall be made for each certificate or by some other system, and what the amount shall be. These certificates impose legal liabilities upon the medical men giving them, and cannot be regarded as medical treatment and attendance. It is, of course, impossible to determine what the number of certificates required will be. In London the percentage of sick absentees on the established staff of the Post Office in 1909 was for males 60 and for females 84. Allowing for repetitions, it is possible that, on the average, each insured person might require one certificate.

Treatment of tuberculosis.—If practitioners on the panel are recognised as persons undertaking treatment of tuberculosis within the meaning of Section 16, a substantial addition to the remuneration from the fund for sanatorium benefit may be anticipated. Further, Section 17 (1) allows the Insurance Committees to extend the special treatment to the dependents of insured persons, and for them obviously extra fees must be paid. The amount available for sanatorium benefit, irrespective of the grant of a million and a half for building, is 1*s.* 3*d.* per insured person. There is no reason

[3] Accounts of Expenditure of Wage-earning Women and Girls.

why a considerable proportion of this should not go to the medical profession.

Maternity benefit.—In estimating remuneration on a capitation basis per insured person, some part of the payment from maternity benefit should be excluded, since it will be paid in many cases in respect of persons outside the 13,000,000. The Chancellor of the Exchequer estimated that £500,000 would go to the medical profession from this source, but the grounds for this opinion were not stated. If fees are raised very much, societies may encourage their members to obtain the services of midwives rather than doctors. The profession should, however, secure a substantial increase in the fees paid for attendance upon cases to which they have been summoned under the Midwives Act of 1902.

LORD LISTER'S FUNERAL.

ON Friday last, Feb. 16th, the body of the late Lord Lister, the greatest Englishman of his century, the master surgeon, was buried at Hampstead Cemetery near that of his predeceased wife. So much his country, which would fain have done him the highest honour that lay in its power by burial in the national Pantheon, was constrained to yield to his own personal wishes. But it claimed at least the prerogative of first paying final homage by a solemn memorial service in the historic great Abbey of Westminster. For Lister was a maker of history, not for England only, but for the human race. No personal skill as a surgeon, however great, could have gained for him the homage and gratitude of the entire world. It was the keen observation, the years of patient questioning of Nature's ways, the illuminating insight, the patient demonstration that finally enabled him to lay a firm foundation for the surgical art—never to be superseded no matter what developments in superstructure it may be called on to sustain—that called forth the splendid tribute of reverence to the remains of Lord Lister from rulers and nations, from the scientists and savants of the earth, and from representatives of every rank and class in life among his own countrymen.

Before 1 P.M. the lantern and choir of Westminster Abbey were filled with official representatives, and a goodly portion of the general public occupied the north transept and aisle and the nave. The King was represented by Sir Frederick Treves, Queen Alexandra by Sir Francis Laking, and Princess Louise (Duchess of Argyll) by Mr. Oswald Balfour. The Prime Minister in person offered the tribute of the nation at large. Austria-Hungary, France, Germany, Italy, and Russia sent their Ambassadors; Belgium, Denmark, Greece, Sweden, Norway, and Portugal their Ministers; the Chinese Minister was represented by Dr. Wu Lien-Teh; and Servia by its Chargé d'Affaires. The Government was represented through the Medical Departments of the Local Government Board and the Board of Education, the Army and Navy Medical Services, and the West African Medical Staff. Representatives of scientific bodies, foreign as well as British, were present; the Swedish Academy of Science, the Norwegian Society of Science, the Madrid Academy of Medicine, the Accademia dei Lincei of Rome, the Imperial Academy of Sciences of St. Petersburg, the British Academy, the Royal Institution, the British Science Guild, the Royal Institute of Public Health, the Hunterian, Royal Microscopical, and Zoological Societies, and Kew Gardens, in addition to those enumerated below which sent special delegates to the procession. The Royal Colleges of Surgeons and of Physicians of the three kingdoms and the Society of Apothecaries were represented, as was every University in Great Britain and Ireland, the medical societies, the Edinburgh and Glasgow University Clubs, the Merchant Taylors' Company, Epsom College, University College of South Wales, the constituent colleges of the University of London, the Norfolk and Norwich Hospital, and the general and special hospitals and medical schools of London, Oxford, Edinburgh, and Glasgow.

The scene in the Abbey during the interval of waiting was truly impressive. A spirit of reverence dwells within those lofty grey walls, and in very truth it hovered over the entire congregation there gathered together. The silence was profound. Notwithstanding a continuous stream of newcomers hardly a sound could be heard, and the demeanour of all was grave. Presently Purcell's exquisite music, composed for the funeral of Queen Mary in 1694, broke in upon the silence from the organ. This was followed by Chopin's "Marche Funèbre," and finally trombones, stationed high up in the triforium, played the Tres Æquali of Beethoven. Then came, faintly at first, the voices of the choir singing the hymn "Brief life is here our portion," as the coffin was borne from the Chapel of St. Faith, where it had rested during the previous night, to a high bier at the foot of the altar rails, surrounded by six burning candles. In the front of the procession came the clergy, with the Dean of Westminster, Bishop Ryle, at their head. A magnificent wreath of orchids and lilies, sent by the German Emperor, and deposited on the coffin by the German Ambassador while it lay in St. Faith's Chapel, was carried in front of the coffin. Splendid wreaths were also displayed at the altar rails from the Institut Pasteur of Paris, the Congress of German Surgeons, and the Medical Society of Amsterdam. The coffin was covered with a purple pall, and on it were laid Lord Lister's three most distinguished orders—the Order of Merit, the Prussian Order Pour le Mérite, and the Grand Cross of the Order of the Danebrog. The pall-bearers, in their various official robes, escorted the body. They were Lord Rayleigh, O.M., representing the Order of Merit; Lord Rosebery, for the University of London; Lord Iveagh, for the Lister Institute; Sir Archibald Geikie, President of the Royal Society; Sir Donald MacAlister, Principal of Glasgow University; Sir Watson Cheyne, Bart., for King's College, London; Mr. Rickman J. Godlee, President of the Royal College of Surgeons of England; and Professor F. M. Caird, for Edinburgh University. Immediately following were the principal mourners, consisting of Mrs. Lister, Mr. and Mrs. J. J. Lister, Dr. A. H. Lister, Mr. and Mrs. W. T. Lister, Miss Lister, Miss E. M. Lister, Miss G. Lister, Dr. and Mrs. A. G. Phear, Mrs. R. J. Godlee, Mr. and Mrs. J. Lister Godlee, Mr. and Mrs. A. Godlee, Mr. F. Godlee, General Burn, Mr. T. Godlee, Miss Godlee, Mr. J. Harold Pim, Mrs. Goodbody, Miss Pim, Miss C. Pim, Mr. A. Lister Harrison, the Right Hon. J. W. Wilson, Mr. and Mrs. Albright, Mr. and Mrs. C. T. Barclay, and Mr. Ernest Beck. The Lord Mayor of London (Sir Thomas Crosby, M.D.) and the Lord Provost of Edinburgh came next, and were followed by the official delegates from various scientific and learned societies. The French Academy of Science sent its President (Professor Lippmann), and also Professor Chauveau and Professor Dastre; the Institut Pasteur of Paris sent Professor Roux; the French Academy of Medicine, Professor Pozzi; the German Congress of Surgeons its President (Professor Garré); the Société de Chirurgie de Paris, Sir Victor Horsley; and the Medical Society of Amsterdam, Professor Treub. The Royal Society of London sent its treasurer, Sir Alfred Kempe; its secretaries, Sir Joseph Larmor, M.P., and Sir John Rose Bradford; and its foreign secretary, Sir William Crookes, O.M.; while the Royal Society of Edinburgh sent Sir James Dewar. The Royal College of Physicians of London sent its President, Sir Thomas Barlow, Bart.; its Senior Censor, Dr. J. Mitchell Bruce; its Registrar, Dr. J. A. Ormerod; and Sir Richard Douglas Powell, Bart. The Royal College of Surgeons of England sent its Vice-Presidents, Mr. C. W. Mansell Moullin and Mr. C. T. Dent; that of Edinburgh, its President, Mr. G. T. Berry; and that of Ireland, its President, Mr. R. H. Woods. The delegates from the University of London were Sir Edward Busk (chairman of Convocation), Sir H. Miers (Principal), and Sir Philip Magnus, M.P.; from the University of Edinburgh, Professor Alexis Thomson; and from the University of Glasgow, the Lord Rector, Mr. Birrell. Other delegates were Sir Henry Morris, President of the Royal Society of Medicine; Mr. Edmund Owen, for the British Medical Association; Sir William Ramsay, President of the British Association; the Bishop of Exeter, Principal the Rev. A. C. Headlam, D.D., and Professor J. M. Thomson, F.R.S., for King's College, London; Sir David Ferrier and Dr. Nestor Tirard for King's College Hospital. University College sent its Provost, Dr. Gregory Foster; and University College Hospital Medical School its Dean, Mr. Raymond Johnson.

The service was brief but impressive. After the Ninetieth Psalm, *Domine, Refugium Nostrum*, had been chanted by the choir to Purcell's music, and the lesson from I. Corinthians, xv., had been read by the Dean, the choir sang Handel's "When the ear heard Him," the concluding sentence of which—"His body is buried in peace, but his name liveth

evermore"—was splendidly appropriate. Goss's anthem, "I heard a voice," followed, and after the prayers had been recited by the Precentor, and the hymn, "O God, our help in ages past," had been sung by the congregation, the procession was reformed and the body borne on the way to its final resting place to the solemn roll of the Dead March in "Saul."

To the onlooker, perhaps, the most significant characteristic of the assembled congregation was the spirit of reverence that seemed to permeate all present. In a mixed assemblage of all religious creeds, containing many, perhaps, owning no creed, official attendance on an important function is commonly satisfied with the preservation of due decorum. In the present instance, however, there was more than that visible in the demeanour of everyone. To those of the Church of England the ever beautiful service spoke its accustomed words of hope, but in a voice of unusual sweetness. Those of other faiths, doubtless, translated its significance into terms of their own. But all at least were alike impressed with that view of immortality which sees the survival of personality in the enduring work of one who devotes his life to furthering the welfare of the human race; and this was particularly evident in the case of him who established the relief of human suffering on an everlasting basis.

OFFICIAL MANUAL OF CAUSES OF DEATH.

IN his Supplement to the Fortieth Annual Report of the Local Government Board, already noticed in these columns,[1] Dr. A. Newsholme foreshadows the removal of some of the defects in our national vital statistics that detract from their usefulness for purposes of sanitary administration.

Sanitary and Registration Districts.

Owing to lack of correspondence between the areas dealt with by the Local Government Board and the National Register Office respectively, comparison among the vital statistics of these areas has hitherto been impracticable. These defects will shortly disappear, for the Registrar-General has undertaken to substitute sanitary districts for registration or Poor-law districts as the areas for which returns of birth and death will be published from the year 1911 onwards.

Moreover, as the coöperation of the Central Statistical Office may presumably be relied on for the calculation of local rates of mortality, we doubt not that in such event the county as well as the district medical officers everywhere will be glad to be relieved of that irksome part of their duty, so that more time may be available for the discharge of their definitely preventive functions.

The medical officer of the Local Government Board further states that the Registrar-General has undertaken to issue to every medical officer of health a "Manual of Causes of Death" which will contain the new standard tables, and will define the contents proper to the various items in the list, showing how each form of death certificate should be classified.

Nature and Object of Manual.

In fulfilment of this undertaking the present manual has been issued by authority of the Registrar-General. The work has been compiled by Dr. T. H. C. Stevenson, the superintendent of statistics, Mr. Bernard Mallet's contribution thereto being limited to a brief minute officially submitting the document to his parliamentary chief. A work on similar lines but more comprehensive in scope has recently been published by Dr. Cressy Wilbur, chief statistician to the United States Census Bureau. It is upon this work, a copy of which lies before us, that the English manual is avowedly based, although in preparing the latter many exclusively American expressions have been omitted, whilst numerous terms have been added which are in common use here but not in the United States.

In projecting the present work it has been the compiler's endeavour to secure the nearest approach to uniformity of tabulation of facts throughout the United Kingdom. For reasons given in the introduction the form of the Scottish and Irish list of causes will not be identical with that of the English list, though the differences will be slight. But in England and Wales complete uniformity will be obtained by the adoption of the standard list at Somerset House and Whitehall respectively, and the use of the same list will doubtless be required in the reports of all medical officers of health. This standard list is already published, and will be circulated with the manual itself among medical officers of health generally. Included in the manual will be found revised suggestions to medical practitioners in filling up their death certificates. We presume that a copy of these suggestions will be sent to every medical practitioner on the Register, and it would certainly be desirable that this should be accompanied by a copy of the manual itself.

Classification of Causes of Death.

In Dr. Stevenson's judgment the only classification of diseases that is essential in a standard list is that it should secure the correct assignment of a given cause to one or other of the included titles. The order of titles in the list he regards as of less importance, inasmuch as that order admits of alteration according to individual requirements, whereas the user has no means of modifying the grouping of death causes under titles.

Readers of the earlier reports of the Registrar-General will be aware that the order of causes originally adopted by Dr. Farr about the middle of last century was based on anatomical rather than on etiological considerations. On this point, however, it seems reasonable to conjecture that Farr's preference may have been determined by the primitive and unsettled state of etiological knowledge at the time. In any event, the author of the present manual has decided to revert to Farr's practice, and he does so on the ground of the greater convenience to statistical students that he believes to attach to a regional as compared with a causal arrangement. Whether this decision is the wisest in the circumstances experience alone can determine. Meanwhile it is due to Dr. Stevenson to note his acknowledgment that "the grouping of causes of death is a subject in regard to which there is room for differences of opinion; and, further, that the individual points which require consideration in preparing such a manual as this are so numerous and in some cases so complicated that it will not be surprising if critical use of the work reveals a number of defects in regard to detail, whether the general principles followed prove acceptable or no."

Criticism of New Departure.

In justification of the action of the Registrar-General's predecessor, who in the year 1901 revised the official list of death causes, it may be pointed out that in so doing he simply followed the example of the Royal College of Physicians of London in the decennial revision of the nomenclature then in course of preparation. On account of the admittedly infective nature of certain diseases, such as pneumonia, cerebro-spinal fever, epidemic diarrhœa, &c., the College deliberately transferred them to the class of "general diseases" from their original places among purely local affections. If the College in its approaching fourth decennial revision, pursues the same course respecting several of the so-called "local" diseases, we shall be in nowise surprised.

Among adverse criticisms of the new departure may be noted one by Sir John W. Moore, of Dublin, the eminent sanitarian and ex-President of the Irish College of Physicians who in a letter to us[2] severely condemns the changes initiated recently in the Registrar-General's mortality returns. The gravamen of his charge is that the transference to merely local affections of such unquestioned acute infections as cerebro-spinal fever, pneumonia, epidemic diarrhœa, and puerperal fever from their rightful position under the heading epidemic diseases places a formidable block in the path of sanitary reformers and medical officers of health. The hands of the State-medicine clock are being put back a quarter of a century at least—to pre-notification days. Writing as a resident in Ireland, Sir John Moore regards with concern a modification in the list of causes of death which will probably delay the inclusion under the Notification Act of such death-dealing yet preventable maladies as pneumonic fever and epidemic diarrhœa.

Continuity with Past National Records.

Dr. Stevenson assures us that the difficulty of arranging for the continuity of official records has been almost entirely overcome by subdividing some of the titles in the new

[1] THE LANCET, Nov. 25th, 1911, p. 1501.

[2] THE LANCET, Jan. 21st, 1911, p. 189.

extended table, which will be published in subsequent annual reports of the Registrar-General, together with the necessary subdivisions of titles in tables of the mortality of the whole country.

Primary and Secondary Causes of Death.

Among other good points in the manual may be noticed an attempt to explain the meaning of the terms "primary," and "secondary" as applied to causes of death in the medical certificates, the official form for which has been revised for use from the year 1911 onwards. The definitions of these terms were adopted after consultation with the Royal College of Physicians of London. They have been designed to secure, as far as possible, that the certifying practitioner, the only person fully qualified to do so, shall select as primary that cause of death which was of greatest importance, and upon which any other related causes mentioned were dependent. In the suggestions to medical practitioners already referred to we read that by "primary cause of death" is meant (in the case of death from disease) the disease present at the time of death which initiated the train of events leading thereto, and not a mere secondary, contributory, or immediate cause, or a terminal condition or mode of death.

A terminal condition or mode of death should not be entered as a secondary (or contributory) cause. In a very large proportion of instances the statement of the primary cause gives all the information required; in these cases nothing is gained by adding as a secondary cause such a condition as "syncope," "heart failure," "coma," "exhaustion." Thus a certificate of "pulmonary tuberculosis" is not improved by the addition of "exhaustion" as a secondary cause; though if a complication such as "pneumothorax" had supervened this should be noted as a contributory cause of death.

We have been led to notice this part of the manual thus fully because it is by no means certain that the Treasury will sanction the circulation of the work to medical practitioners generally, although they are called upon to supply gratuitously the indispensable information respecting the cause of death which they alone possess. Quite significant in this regard is the fact that the price of the manual (1*s.*) is printed on the cover.

REPORTS ON PLAGUE INVESTIGATIONS IN INDIA

ISSUED BY THE ADVISORY COMMITTEE APPOINTED BY THE SECRETARY OF STATE FOR INDIA, THE ROYAL SOCIETY, AND THE LISTER INSTITUTE OF PREVENTIVE MEDICINE [1]

Epitome of Some Recent Observations on Rat Fleas.

THE chief points noted in this summary of recent work on rat fleas elsewhere than in India are: 1. English field rats harbour C. fasciatus and Ct. agyrtes in about equal numbers. 2. The tropical rat flea (X. cheopis) has been found on rats at Guy's Hospital in London in abundance. 3. The work of Chick and Martin shows that C. fasciatus feeds on man about as readily as on the rat or rabbit; the common mouse flea (Ct. musculi) and Ct. agyrtes, on the other hand, bite man hardly or not at all. 4. Observations in Marseilles by Gauthier and Raybaud, in Sydney by Tidswell, and in Japan by Kitasato show that at each place there is a seasonal variation in the prevalence of rat fleas, especially of X. cheopis, and that the maximum abundance of fleas is found at the time of year when plague epidemics in man mostly prevail in the given locality.

Preliminary Observations on an Anti-plague Serum.

Preliminary observations on the protective and curative value for rats of the serum of a horse immunised with a toxic nucleo-proteid extracted from the plague bacillus have been made by Dr. Sydney Rowland. The serum prepared possessed, when tested on rats, considerable antitoxic value, 1 c.c. neutralising about 100 fatal doses of the toxic nucleo-proteid with which the horse had been inoculated. It also had a good prophylactic value against infection with living plague bacilli, 1 c.c. protecting every animal, and 1/10 c.c. 7 out of 10 rats, against a dose of plague bacilli inoculated 24 hours later which killed 80 per cent. of untreated rats. The serum was also efficacious in a curative way when administered subsequent to infection, and it is shown to save the lives of a sensible proportion of infected rats even when given as long as 24 hours after infection. This is the more remarkable since the control rats, inoculated but untreated with serum, begin to die on the second day.

Second Report on Investigations into Plague Vaccines.

Dr. Rowland continues his studies of the toxic nucleo-proteid which he has extracted from the plague bacillus and which, as he has previously shown, acts as a highly efficient vaccine in rats in doses so small as 1/1000th milligramme. This nucleo-proteid forms loose compounds with chloroform and toluol, which are relatively non-toxic and are easily reversible; these compounds have greatly diminished immunising power. The effect of heat on the toxic and immunising powers of the nucleo-proteid is much less if the whole bacillus is heated before extraction than when the extracted nucleo-proteid is heated in solution in dilute saline. Extracts of the plague bacillus contain an active proteolytic enzyme. If this be allowed to act on the nucleo-proteid the immunising power at first increases and then remains steady for some months; the toxic value, on the other hand, diminishes progressively, so that after some time the hydrolysed extract is relatively non-toxic, but still forms a very efficient vaccine both against toxic nucleo-proteid and against infection with live bacilli. Hence the protective and toxic properties of such an extract of plague bacilli are distinct.

Statistical Investigation of Plague in the Punjab. Second and Third Reports.

Dr. M. Greenwood continues his statistical analysis of the data collected by the late Major George Lamb, I.M.S., on the occurrence of plague in the villages of the Punjab and United Provinces. Investigating the influence of proximity to railways, he finds that in districts containing large cities, villages near a line of railway are liable to a higher rate of plague epidemics than villages, similar in size and other respects, not so situated. This is probably due to increased opportunities for personal transit rather than to the movement of merchandise, since in purely or mainly agricultural districts proximity to railways does not entail any increased liability to plague infection. It is also shown that large villages tend to be infected earlier in the plague season than small villages; that the mortality from plague tends to be greater the earlier a village is infected; and that in nearly all cases large villages, when infected, suffer less heavily than smaller communities. There is some evidence that the same difference between large and small places obtained in England in the fourteenth to seventeenth centuries. Analysis of the possible explanations leads to the conclusion that the difference in mortality depends upon some material factor which varies with the size of the community rather than on the random incidence of plague infection on a population living in aggregates of varying size.

Observations on Plague in Eastern Bengal and Assam.

The province of Eastern Bengal and Assam has suffered very little from bubonic plague, although it is in close proximity to heavily infected districts in Bengal (Calcutta, Saran). Imported cases from these districts have from time to time given rise to small outbreaks of pneumonic plague, but no bubonic epidemic has arisen. The Commission has made an inquiry lasting over a year into the conditions which might determine this immunity. In Dacca an investigation was undertaken for the whole 12 months into the prevalence of rats and fleas, and other places were visited for short periods. It appears that the freedom of the province from plague can be attributed chiefly to the scarcity of rats in the houses. Per 100 traps set, from 1 to 9 Mus rattus were caught in different places, as compared with 20 to 50 in Poona, Belgaum, Punjab villages, and other heavily infected localities. This comparative scarcity of rats seems to be due partly to the habits of the people, who are comparatively clean, neat, and tidy in their household arrangements, and partly to the structure and disposition of the houses, which are either too well built or too flimsy to afford much shelter for rats. In many places, also, the houses are widely separated from one another. The Commission visited also the neighbouring town of Bhagalpur in

[1] Journal of Hygiene, vol. xi., 1911. Supplement, pp. 1-206. Accounts of previous reports will be found in THE LANCET of Nov. 3rd, 1906, p. 1233; July 27th, 1907, p. 246; Jan. 25th, 1908, p. 253; and Dec. 3rd, 1910, p. 1640.

Bengal, which has suffered rather severely from epidemic plague on several occasions; here were found the more usual ill-built, crowded, and dirty houses with mud walls, and 34 rats were caught for every 100 traps set. Rat fleas were found to be about as common as elsewhere in India, varying from 2 to 8 per rat in different places. In Dacca weekly observations showed that there was a distinct seasonal variation in the prevalence of fleas, the maximum falling in April—i.e., in the plague season as judged by the seasonal prevalence of plague in Calcutta (160 miles distant).

Observations on the Breeding of Mus Rattus in Captivity.

To breed wild rats successfully in captivity it was found necessary to have a separate hut for each pair. If several pairs were confined in the same hut, provided with artificial burrows, &c., not only were young never produced but on being killed the females were never found pregnant. Under appropriate conditions, however, an active pair will produce from 29 to 44 young per annum; the commonest number in a litter is 6, with an average interval of 56 days. The young will breed when 5 months old, probably earlier, and in the absence of any mortality it may be calculated that a single pair will increase to 198 in 12 months and 858 in 16 months. Interesting data are given with regard to the rate of growth of young rats in length and weight; up to about 100 grammes weight (14 weeks) they grow about 1 gramme per day, weighing 4 grammes at birth.

Major George Lamb, M.D. Glasg., I.M.S.

An obituary notice is given of this distinguished officer of the Indian Medical Service, who had been associated with the work of the committee since its commencement in 1905, for the most part as officer in senior charge of investigations in India.

MEDICINE AND THE LAW.

Action arising out of the Sale of a Medical Practice.

AT the recent Devon assizes Mr. Justice Darling with a special jury tried an action brought by the executors of the late Mr. J. Gordon against Mr. J. W. Winterburn for £200 alleged to be due under an agreement for the purchase of the medical practice of the former, or in the alternative for damages for breach of an agreement to purchase. The defendant alleged that he was induced to enter into the agreement by misrepresentation and counterclaimed that it should be rescinded. The case was opened by counsel for the defendant in support of the counterclaim to the effect that the defendant desiring to purchase a medical practice was attracted by an advertisement in THE LANCET, which described as for sale an "unopposed country practice; appointments about £90; scope for increase; residence available with land; low rates; inclusive rental £26" The defendant accordingly inspected the place and had interviews with the plaintiffs, when he was informed that another medical practitioner residing in the neighbourhood had retired and was occupying himself with farming, being also told that this gentleman had looked after the patients of the deceased at a time when he had been incapacitated by an accident. The defendant did not inspect the books of the deceased as he was told they were badly kept, but was given particulars of two appointments as medical officer to guardians, two clubs, and vaccination fees, which were estimated to be of a total value of £80 or £90 a year. The whole of the earnings of the late occupant of the practice were put down as about £230 per annum, no mention being made of opposition. The defendant after further negotiations agreed to pay £300 for the practice, and did pay down £100. Later, when he had entered upon practice the guardians declined his application for the appointments, which amounted to only £37 15*s*, and advertised them; he found the total of the private practice of the deceased to have been considerably less than alleged, and that Dr. G. R. Ayshford, the medical man already mentioned, was in fact practising. He eventually was informed by Dr. Ayshford that the deceased had given way to the drug habit and had lost practice thereby, and eventually agreed to go into partnership with Dr. Ayshford, upon terms which enabled him to secure one of the Poor-law appointments originally spoken of. In his evidence the defendant laid stress upon the statements that the practice was unopposed, and upon the amount alleged for the appointments available as being the misrepresentations of which he particularly complained. Evidence as to the value of these and as to the practice of the deceased was given. For the plaintiffs, evidence was given to the effect that the advertisement in THE LANCET quoted above was an old one used for the sale of the practice when the deceased bought it, which had been repeated through an error, and that the defendant had been fully informed of its inaccuracies by the executors. It was also stated that he had been told that Dr. Ayshford attended patients, reference being made to his doing this in some cases as locum tenens for Mr. Gordon, with the suggestion that he might not retain these. At the close of the case Mr. Justice Darling left the following questions to the jury, who gave the answers appended: 1. Did the plaintiffs make Mr. Winterburn the misrepresentations alleged?—Yes. 2. If so, was Mr. Winterburn thereby induced to agree to buy the practice of the late Mr. Gordon and to pay £100 as part of the price?—Yes. 3. Has Mr. Winterburn had and kept any part of what he agreed to buy?—Yes. (This refers to the defendant having remained in the district after entering into partnership with Dr. Ayshford.) 4. If so, what is the value of what he has had and kept?—£120, including £100 paid as deposit. Judgment was not given, the consideration of the precise effect of the jury's findings being reserved for argument at a later date in London.

Summoning a Medical Man in an Emergency.

An inquest was held recently in the Westminster coroner's court upon the body of a lady engaged in journalism and residing by herself in chambers in Davies-street, Berkeley-square. There was no doubt upon the medical and other evidence that the deceased had shot herself with a revolver, which she kept to the knowledge of her friends for the purpose of self-defence, and the verdict of the jury was probably a correct one—that she had met with accidental death while handling the weapon in question. Frequent protest has been made in THE LANCET against the carrying of revolvers in public, but the keeping of a firearm by a lady living alone, with a view to a possible emergency, such as the visit of a burglar, is, of course, a different matter. A revolver, in such circumstances, may some day prove a valuable protection, but its value will depend upon expert handling, and its owner should render herself familiar with its use, never forgetting the danger of manipulating it carelessly. In the instance under comment two of the witnesses who knew that the deceased owned such a weapon were not able to say that she had ever fired it, and one of them was of the opinion that she knew very little about its use, although she kept it loaded by her bedside. A feature of this case, however, of more interest to the public and to medical practitioners than the use or abuse of pistols, consists in the fact that in the middle of the West-End of London one of the witnesses, a lady friend of the deceased, who found her lying wounded and hastened to summon a medical man, was apparently engaged for about an hour in scouring the neighbourhood in a taxicab in order to find one. The conditions were peculiar as to time and locality, for the shooting took place about 5 P.M. on a Sunday, and, as we have said, in Davies-street, Berkeley-square. It will readily be realised that in almost all the nearest streets the number of brass plates on the front doors would appear to suggest an abundant supply of surgical aid for any person seeking for it, but in fact the number of gentlemen at hand and ready to respond to such a call proved to be extremely small. According to the evidence, the witness tried Brook-street, Bruton-street, Jermyn-street, and Harley-street before securing the assistance of Mr. Walter Wise from George-street, Portman-square, who about 6.30 P.M. found the deceased moribund, and afterwards gave evidence at the inquest. The difficulty might not have occurred if the deceased had had occasion to consult a general practitioner in her neighbourhood, but it must be remembered that a young lady in good health may not even know the name of any medical man resident within a mile of her dwelling, and that on a Sunday afternoon, with the shops closed and the streets empty, it would be doubly difficult to obtain the desired information. At the shop of a pharmaceutical chemist, where, on Sundays as well as on week days, prescriptions are made up for applicants, the address might have been obtained of a surgeon known to be at home, but it is fortunate that urgent

occasions corresponding exactly with that described do not very often arise.

The Sale of Indecent Publications: Another Prosecution.

At Bow-street recently, before Mr. Curtis Bennett, the Phœnix Press, Limited, were summoned for sending through the post a packet containing prints of an improper character, the subject matter of the prosecution being three copies of the periodical *Photo Bits*, dated Dec. 23rd and 30th, 1911, and Jan. 13th, 1912. Mr. Curtis Bennett, in imposing a fine of £10, with 20 guineas costs, observed that papers of this class were circulated amongst the young to the detriment of their morals, and that it was time that such a thing should be stopped. To his mind, from the first sheet to the last, these papers were produced for one purpose only—the suggestion of evil. The illustrations, one and all, were of a most suggestive and loathsome character, and to suggest that the directors of the company were not responsible was not fair to the manager, who was there to do what he was paid for.

We may add that in opening the case against the defendants Mr. Muskett had made particular allusion to the objectionable character of the advertisements inserted, and had referred to the fact that the Home Secretary on Jan. 23rd promised that a Bill would soon be introduced dealing with the whole subject, and had complained of the difficulty which, under the existing law, attends any attempt to punish promptly and effectively those responsible for publications of the class complained of. It will be noticed that the proceedings in question were brought under the Post Office Act in consequence of this difficulty. Those who hope to see the Home Secretary's promise fulfilled may be warned not to be too sanguine. In THE LANCET of Oct. 31st, 1908, comment was made upon the report of the Joint Select Committee which had then recently considered the whole question of indecent publications and of advertisements which recommend, under a veil of words too thin to deceive anyone, drugs intended to be bought by pregnant women for use as abortifacients. No Bill upon the subject has yet been introduced by Government, although it could hardly be one likely to excite violent opposition or of very great length or complexity.

The subject was referred to again more recently in THE LANCET of July 31st, 1909, when prosecutions instituted in respect of a paper named *Photo Fun* had resulted in convictions and the imposition of fines. *Photo Bits* was mentioned on this occasion during the prosecution of a newsvendor as the subject of a search warrant, so that its proprietors must have been aware, apart from their knowledge of its contents, that it was attracting the attention of the authorities. Their trade, however, is not likely to be seriously interfered with until objectionable matter in the body of a periodical and in its advertisements is fully defined in an Act of Parliament, and until power is given to inflict imprisonment upon summary conviction in aggravated cases upon those responsible for either publication or sale. Fines are of little avail, and when incurred by newsvendors are readily paid by those who make a profit by publishing this kind of garbage.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 94 largest English towns having an estimated population of 17,559,219 persons in the middle of this year, 9096 births and 6270 deaths were registered during the week ending Feb. 17th. The annual rate of mortality in these towns, which had steadily increased from 14·8 to 21·6 per 1000 in the four preceding weeks, declined to 18·6 in the week under notice. During the first seven weeks of the current quarter the mean annual death-rate in these large towns averaged 17·3 per 1000, while in London during the same period the annual death-rate did not exceed 16·6 per 1000. The annual death-rates last week in the several towns ranged from 6·2 in Southend-on-Sea, 8·5 in Hornsey, 9·2 in Wimbledon, 9·9 in Enfield, and 10·0 in Ilford, to 27·5 in Preston, 28·5 in Bath, 29·6 in West Bromwich, 35·1 in Great Yarmouth, and 37·5 in Dudley.

The 6270 deaths from all causes in the 94 towns were 1006 fewer than the number recorded in the previous week, and included 365, which were referred to the principal epidemic diseases, against numbers rising from 297 to 435 in the four preceding weeks. These 365 deaths from the principal epidemic diseases included 148 from whooping-cough, 69 from measles, 58 from infantile diarrhœa, 43 from diphtheria, 28 from scarlet fever, and 19 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 1·1 per 1000, against 1·2 and 1·3 per 1000 in the two previous weeks. The deaths attributed to whooping-cough, which had steadily increased from 81 to 186 in the four preceding weeks, fell to 148 last week, and caused the highest annual death-rates of 1·8 in Bury, 1·9 in Devonport, 2·2 in Preston, 2·4 in Barrow-in-Furness, 3·2 in Merthyr Tydfil, and 3·9 in Walsall. The deaths referred to measles, which had been 72, 63, and 98 in the three preceding weeks, declined to 69 last week; the highest annual death-rates from this cause were 1·2 in Reading, 1·3 in York, 2·1 in Warrington, and 2·4 in Nottingham. The fatal cases of infantile diarrhœa, which had been 47, 67, and 49 in the three previous weeks, slightly rose to 58 last week, and included 19 in London and its suburban districts, 7 in Manchester, and 6 in Liverpool. The deaths attributed to diphtheria, which had been 53, 71, and 64 in the three preceding weeks, fell to 43 last week, and of this number 13 were registered in London and its suburban districts, and 3 in Portsmouth. The deaths referred to scarlet fever numbered 28, and were 6 in excess of the average in the six preceding weeks; 3 deaths were recorded in Liverpool, and 2 each in London, Stoke-on-Trent, Birmingham, Warrington, Leeds, and Aberdare. The fatal cases of enteric fever, which had been 13 and 16 in the two preceding weeks, further rose to 19 last week, and included 3 in London and 2 each in Stoke-on-Trent, Birmingham, Leeds, Sheffield, and Hull.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had been 1562, 1500, and 1512 in the three preceding weeks, had further declined to 1461 on Saturday last; 154 new cases of this disease were admitted to these institutions during the week, against 158, 169, and 178 in the three preceding weeks. These hospitals also contained on Saturday last 1148 cases of diphtheria, 390 of whooping-cough, 180 of measles, 55 of enteric fever, and 2 of small-pox. The 1564 deaths from all causes registered in London were 198 fewer than the number in the previous week, and were equal to an annual death-rate of 18·0 per 1000. The deaths referred to diseases of the respiratory system, which had steadily increased from 290 to 545 in the five preceding weeks, declined to 440 in the week under notice, but were 19 in excess of the number recorded in the corresponding week of last year.

Of the 6270 deaths in the 94 large towns, 195 resulted from different forms of violence, and 474 were the subject of coroners' inquests. The causes of 54, or 0·9 per cent., of the deaths registered last week were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Manchester, Sheffield, Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, Nottingham, and in 57 other smaller towns. The 54 uncertified causes of death last week included 7 in Liverpool, 6 in Birmingham, 3 in West Bromwich, 3 in South Shields, and 3 in Gateshead.

HEALTH OF SCOTCH TOWNS.

In the 18 largest Scotch towns, having an estimated population of 2,182,400 persons in the middle of this year, 1108 births and 923 deaths were registered during the week ending Feb. 17th. The annual rate of mortality in these towns, which had increased from 17·3 to 22·8 per 1000 in the four preceding weeks, declined to 22·1 per 1000 in the week under notice. During the first seven weeks of the current quarter the mean annual rate of mortality in these towns averaged 19·2 per 1000, and was 1·9 per 1000 in excess of the mean rate recorded during the same period in the 94 large English towns. The annual death-rates in the several Scotch towns last week ranged from 12·2 in Leith, 12·9 in Clydebank, and 13·7 in Partick, to 25·7 in Glasgow, 26·8 in Greenock, and 33·2 in Perth.

The 923 deaths from all causes were 30 fewer than the number in the preceding week, and included 103 which were referred to the principal epidemic diseases, against 100 in each of the two preceding weeks. Of these 103 deaths, 63

resulted from measles, 14 from whooping-cough, 14 from infantile diarrhœal diseases, 6 from diphtheria, 4 from enteric fever, and 2 from scarlet fever, but not one from small-pox. These 103 deaths from the principal epidemic diseases were equal to an annual death-rate of 2·5 per 1000, or 1·4 per 1000 above that recorded in the 94 large English towns. The deaths attributed to measles, which had increased from 39 to 62 in the three preceding weeks, were 63 last week, and included 42 in Glasgow, 9 in Greenock, and 4 in Edinburgh. The deaths referred to whooping-cough, which had been 14 in each of the two preceding weeks, were again 14 last week; and of this number 3 deaths occurred in Glasgow, 3 in Greenock, 2 in Aberdeen, and 2 in Ayr. The fatal cases of infantile diarrhœa, which had been 11, 13, and 6 in the three preceding weeks, rose to 14 last week; 4 deaths were registered in Glasgow and 4 in Edinburgh. The deaths attributed to diphtheria, which had been 12 and 13 in the two previous weeks, declined to 6 last week, of which 3 were recorded in Glasgow. The 4 deaths referred to enteric fever were 2 in excess of the number in the previous week, and included 2 deaths in Glasgow. The 2 fatal cases of scarlet fever were registered in Glasgow and Kirkcaldy respectively.

The deaths referred to diseases of the respiratory system, which had steadily increased from 120 to 220 in the four preceding weeks, slightly declined to 209 in the week under notice; and 30 deaths were attributed to different forms of violence.

HEALTH OF IRISH TOWNS.

In the 22 town districts of Ireland, having an estimated population of 1,157,014 persons in the middle of this year, 679 births and 590 deaths were registered during the week ending Feb. 17th. The annual rate of mortality in these towns, which had steadily increased from 18·0 to 31·0 per 1000 in the seven preceding weeks, declined to 26·6 per 1000 in the week under notice. During the first seven weeks of the current quarter the mean annual death-rate in these Irish towns averaged 23·6 per 1000; in the 94 large English towns the mean annual death-rate during the same period did not exceed 17·3 per 1000, while in the 18 Scotch towns it was equal to 19·2 per 1000. The annual death-rates in the several Irish towns last week were equal to 23·9 in Dublin (against 18·0 in London), 33·1 in Belfast, 26·5 in Cork, 16·6 in Londonderry, 21·7 in Limerick, and 30·4 in Waterford; while in the 16 smallest of these Irish towns the death-rate last week was equal to 21·3 per 1000.

The 590 deaths from all causes in the 22 Irish towns were 98 fewer than the number in the previous week, and included 42 which were referred to the principal epidemic diseases, against 31 and 49 in the two preceding weeks; of these 42 deaths, 21 resulted from whooping-cough, 8 from measles, 8 from infantile diarrhœal diseases, 2 from enteric fever, 2 from scarlet fever, and 1 from diphtheria, but not one from small-pox. These 42 deaths from the principal epidemic diseases were equal to an annual death-rate of 1·9 per 1000; the death-rate last week from these diseases did not exceed 1·1 per 1000 in the 94 large English towns, while in the 18 Scotch towns it was equal to 2·5. The deaths attributed to whooping-cough, which had been 15, 15, and 25 in the three preceding weeks, declined to 21 last week, of which 17 were recorded in Belfast and 2 in Cork. The deaths referred to measles, which had been 2 and 5 in the two preceding weeks, rose to 8 last week, and included 4 in Cork and 3 in Dublin. The 8 fatal cases of infantile diarrhœa were equal to the number in the previous week; 4 deaths were registered in Dublin and 2 in Waterford. The 2 fatal cases of enteric fever were recorded in Belfast; those of scarlet fever in Limerick and Galway respectively; and that from diphtheria in Dublin.

The deaths referred to diseases of the respiratory system, which had steadily increased from 83 to 239 in the eight preceding weeks, declined to 212 in the week under notice. Of the 590 deaths from all causes in the 22 Irish towns last week, 181, or 31 per cent., occurred in public institutions, and 14 resulted from different forms of violence. The causes of 20, or 3·4 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 94 large English towns the proportion of uncertified causes of death last week did not exceed 0·9 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

IN accordance with the provisions of Order in Council of April 1st, 1881, Fleet-Surgeon Alfred Harold Lissant Cox has been placed on the Retired List, at his own request (dated Feb. 6th, 1912).

The following appointments have been notified:—Fleet-Surgeon J. Shand to the *Shannon*, on recommissioning. Staff-Surgeons: J. C. Bringan to the *Victory*, for disposal; A. R. H. Skey to the *Roxburgh*; A. A. Sanders to the *Vivid*, additional, for disposal, to be lent to the *Gossamer*, and for duty with the *Circe*, *Seagull*, and *Speedwell*.

THE ROYAL NAVAL VOLUNTEER RESERVE.

Donald John Forbes has been appointed Surgeon (dated Feb. 9th, 1912).

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel George F. Gubbin is placed on retired pay (dated Feb. 19th, 1912).

Major Anthony J. Luther to be Lieutenant-Colonel, vice G. F. Gubbin (dated Feb. 19th, 1912).

The undermentioned Majors to be Lieutenant-Colonels:—Robert J. Copeland, vice R. G. Hanley, deceased (dated Jan. 30th, 1912). John Girvin, vice F. P. Nichols, retired (dated Feb. 9th, 1912).

The undermentioned Lieutenants are confirmed in their rank:—Hugh G. Monteith, John S. Levack, Tom C. R. Archer, Basil H. H. Spence, Edward S. Calthrop, Robert Davidson, Herbert S. Blackmore, James M. Elliott, Douglas W. Bruce, Richard T. Vivian, Edward G. H. Cowen, Leonard Buckley, William L. Webster, Stanley P. Sykes, Henry J. G. Wells, Ernest C Deane, Frank S. Tamplin, Ivor R. Hudleston, William Stewart, Alexander G. J. MacIlwaine, and Arthur S. Heale.

Surgeon-General T. M. Corker has been appointed Principal Medical Officer of the Sixth (Poona) Division, vice Surgeon-General J. G. MacNeece, C.B., on transfer to the home establishment. Colonel M. W. Kerin, C.B., principal medical officer of the Seventh (Meerut) Division, has been appointed Principal Medical Officer of the Eighth (Lucknow) Division. Lieutenant-Colonel C. E. Nichol, D.S.O., commanding the station hospital at Maymyo, has on promotion been selected for appointment as Principal Medical Officer of the Presidency and Assam Brigades, vice Colonel E. Butt, transferred as Principal Medical Officer of the Seventh (Meerut) Division. Lieutenant-Colonel N. Manders, on return from Ceylon, has been appointed in charge of the Military Hospital at the Curragh and in command of No. 17 Company of the Royal Army Medical Corps, in succession to Lieutenant-Colonel G. F. Gubbin on retirement from the service. Lieutenant-Colonel R. H. Hall, senior medical officer at Bermuda, has been selected for the increased rate of pay under Article 317 of the Royal Warrant. Lieutenant-Colonel S. Hickson, on return from a tour of service in South Africa, has been selected for appointment to hold charge of the Cambridge Hospital at Aldershot.

Major I. A. O. MacCarthy has been appointed Recruiting Medical Officer in the London District. Major A. W. Bewley, lately commanding the station hospital at Landour, Mussooree Hills, has joined at Meerut Cantonment for duty. Major S. H. Withers has been transferred from Gharral to the Station Hospital at Ambala. Major J. J. W. Prescott, D.S.O., Adjutant of the Northumbrian Division, School of Instruction, Royal Army Medical Corps, at Newcastle, has been appointed to the Southern Command. Major J. P. Silver, from Edinburgh, has been posted to the Dublin District for duty. Major P. McKessack, on return from Mauritius, where he was employed as sanitary officer, has been appointed Sanitary Officer of the South Thames area of the Eastern Command, vice Major C. H. Stratton, whose tenure of the appointment has expired. Major F. A. Symons, from Ceylon, has joined for duty in the Southern Command. Major H. S. Taylor has arrived home for duty from the Straits Settlements. Major L. Wood and Major A. A. Seeds have embarked for a tour of service in India.

Captain J. Tobin, at present in charge of the Military Families Hospital at Devonport, has been placed under orders for service at Gibraltar. Captain E. W. Powell, on return from Aden, has been appointed to the Irish Command for

duty in the Cork District. Captain A. T. Frost, from the Royal Infirmary, Phœnix Park, Dublin, has been selected for attachment to the Royal College of Surgeons, Ireland, Contingent of the Senior Division, Officers Training Corps. Captain W. F. B. Loughnan, specialist in the prevention of disease Bareilly Brigade, has been granted eight months' leave of absence home. Captain R. L. Argles has joined the Station Hospital at Aden. Captain R. J. Buchanan has been transferred from the Military Hospital at Cosham to the Royal Victoria Hospital, Netley. Captain H. G. Sherren has been posted to the Aldershot Command on his return from India. Captain P. Davidson, D.S.O., has taken up duty as Adjutant at the Royal Army Medical Corps Depôt, Aldershot, in succession to Major F. S. Irvine, transferred to the London District and appointed Assistant to the Commandant, Royal Army Medical College, Grosvenor-road, London. Captain H. A. Bransbury has embarked for India.

The following lieutenants have been appointed for duty in the Irish Command:—R. T. Vivian, H. J. G. Wells, and W. L. Webster. Lieutenant W. A. Frost has been appointed to Tregantle from Devonport. Lieutenant R. C. Paris, from the Royal Victoria Hospital, Netley, has embarked for a tour of service in India. Lieutenant W. Bisset, from Hounslow, has been posted to the Royal Herbert Hospital at Woolwich. Lieutenant S. W. Kyle has been transferred from Jhansi to the Station Hospital at Jubbulpore. Lieutenant W. T. Graham, from the Military Hospital, Tidworth Park, Salisbury Plain, has joined at Birmingham. Lieutenant J. A. Manifold has embarked for a tour of service in Bermuda.

INDIAN MEDICAL SERVICE.

The King has approved of the admission of the undermentioned Lieutenants on probation (dated Jan. 27th, 1912):—Ronald Herbert Candy, Philip John Veale, Henry Hingston, Jamasji Cursetji Bharucha, Frederick Jasper Anderson, Heerajee Jehangir Manockjee Cursetjee, John Simson Stuart Martin, Peter Fleming Gow, Robert Victor Morrison, Jogesh Chandra Dey, James Walker Jones, and James Hall Hislop.

The King has approved of the confirmation of the commissions of the following Lieutenants on probation with effect from July 29th, 1911:—John Alexander Sinton, Edward Randolph Armstrong, Denis Fitzgerald Murphy, Charles James Stocker, Eric Edward Doyle, Cyril Macdonald Plumptre, Archibald Wallace Duncan, Leon Francis Brandenbourg, John Edward Scudamore, Henry Lewis Barker, Edward Austen Penny, and George Benkhorn Harland.

Surgeon-General W. B. Bannerman has been appointed an Additional Member of the Legislative Council of the Governor of Madras Presidency. Lieutenant-Colonel T. E. Dyson has been granted one year's leave of absence home from India. Lieutenant-Colonel A. Coleman has handed over charge of the duties of Superintendent of the Rawal Pindi District Jail to Captain C. A. Gill.

Major J. W. F. Rait has been granted an extension of furlough for four months by His Majesty's Secretary of State for India. Major M. Corry has handed over charge of the duties of Superintendent of the District Jail at Ludhiana to Captain J. G Swan. Major W. E. Scott-Moncrieff, Agency Surgeon of the Second Class, Bengal Presidency, has been granted leave of absence home from India for two years. His Excellency the Governor of Bombay in Council has been pleased to appoint Major A. Hooton to officiate as Civil Surgeon at Poona, vice Lieutenant-Colonel J. B. Smith, proceeding on leave. Major E. S. Peck has assumed charge of the duties of Superintendent of the District Jail at Jullundur, vice Captain H. C. Keates. Major A. F. W. King has been appointed to officiate as Health Officer of the Port and Civil Administrative Medical Officer at Aden during the absence on leave of Lieutenant-Colonel S. E. Prall. Major G Hutcheson, Civil Surgeon at Aligarh, has been granted six weeks' privilege leave of absence.

Captain W. M. Houston has been appointed to officiate as Medical Officer in charge of the Kathiawar Political Agency and in charge of the West Hospital at Rajkot. Captain R. B. S. Sewell, Surgeon Naturalist to the Marine Survey of India, has been appointed to officiate as Professor of Biology at the Medical College, Calcutta, during the absence on leave of Captain R. E. Lloyd. The services of Captain P. Heffernan have been placed at the disposal of the Government of Madras. Captain F. T. Thompson has been granted six months' leave of absence on the recommendation of a medical board. Captain J. E. Clements has been appointed to officiate as Superintendent of the Central Jail at Fategarh, vice Lieutenant-Colonel E. Jennings, granted leave. Captain M. J. Quire has been appointed Professor of Materia Medica at the Madras Medical College. The services of Captain C. C. Shaw have been placed at the disposal of the Chief Commissioner of the Central Provinces. Captain W. P. G. Williams has been appointed to officiate as Superintendent of the Central Jail at Bareilly during the absence on leave of Major C. B. Prall. Captain R. B. Nicholson has been granted one year's leave of absence home from India. Captain J. W. McCoy has been appointed Civil Surgeon at Dinajpur.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

The undermentioned Lieutenants are confirmed in their rank:—Gilbert K. Aubrey, Charles C. Jones, and Henry M. Buchanan.

TERRITORIAL FORCE.

Royal Army Medical Corps.

2nd East Lancashire Field Ambulance, Royal Army Medical Corps: Lieutenant Thomas Carnwath resigns his commission (dated Feb. 14th, 1912).

2nd West Riding Field Ambulance, Royal Army Medical Corps: Lieutenant Charles W. Eames to be Captain (dated Jan. 1st, 1912).

3rd Welsh Field Ambulance, Royal Army Medical Corps: The undermentioned officers to be Captains (dated Dec. 25th, 1911):—Lieutenant Daniel E. Evans and Lieutenant Ernest Brice. Lieutenant George D. E. Jones to be Captain (dated Jan. 7th, 1912).

4th Northern General Hospital, Royal Army Medical Corps: The undermentioned officers resign their commissions (dated Feb. 14th, 1912):—Captain John T. Collier, Captain Harold C. Harrison, and Captain Percy C. Phillips.

3rd West Riding Field Ambulance, Royal Army Medical Corps: Captain (Honorary Captain in the Army) Frederick A. Hadley to be Major (dated Nov. 15th, 1911).

1st South Midland Mounted Brigade Field Ambulance, Royal Army Medical Corps: Lieutenant Thomas H. Forrest to be Captain (dated Jan. 31st, 1912).

3rd London General Hospital, Royal Army Medical Corps: The under-mentioned officers resign their commissions (dated Feb. 21st, 1912):—Lieutenant-Colonel Sir Thomas Barlow, Bart., K.C.V.O, Major Augustus J. Pepper, Captain Henry A. Caley, Captain Horace S. Collier, and Captain Rupert T. H. Bucknall.

2nd London Sanitary Company, Royal Army Medical Corps: Percy Norman Cave to be Lieutenant (dated Jan. 9th, 1912).

Attached to Units other than Medical Units.—Lieutenant John C. S. Burkitt to be Captain (dated Nov. 15th, 1911). Lieutenant Reginald W. Ironside resigns his commission (dated Feb. 21st, 1912). Captain John A. Gibb resigns his commission (dated Feb. 21st, 1912).

For Attachment to Units other than Medical Units.—James Hamilton (late Captain, 5th Battalion, The Queen's Own (Royal West Kent Regiment) to be Captain (dated Feb. 3rd, 1912) Douglas Larmer Wall to be Lieutenant (dated Feb. 21st, 1912).

ROYAL ARMY MEDICAL CORPS (EASTERN COMMAND) TRAINING STAFF TOUR.

The following officers of the Royal Army Medical Corps stationed in the Eastern Command have been directed to attend a staff tour to be held at Guildford from Feb. 26th to 29th:—Lieutenant-Colonel M. O'Halloran, in charge of the Military Hospital at Canterbury; Lieutenant-Colonel F. S. Le Quesne, V.C., in charge of the Auxiliary Hospital at Woolwich; Major F. W. Begbie (Colchester), Major J. C. Jameson (Woolwich), Major H. E. Staddon (Shorncliffe), Major M. M. Rattray (Brighton), Major R. H. Fuhr, D.S.O. (Woolwich), and Major E. B. Knox (Norwich) The object of the tour is chiefly to study the modification which the recently introduced system of supply and transport may entail in the working of the medical services on active service.

The King has fixed Saturday, June 22nd, for an inspection of the St. John Ambulance Brigade in Windsor Park.

Correspondence.

"Audi alteram partem."

LEISHMANIA AND MOSQUITOES.

To the Editor of THE LANCET.

SIR,—Captain J. Hay Burgess, I.M.S., in a criticism of Professor Franchini's work, to which he himself will answer if he thinks it necessary, uses the following sentence: "I note that such is the heading of his article. *Leishmania infantum and Leishmania donovani are not synonymous terms.*" As Professor Franchini, voluntary assistant in my institute, has published other contributions on leishmania, cultivated from spleen juice of kala-azar patients, it is well that Captain Hay Burgess should know: 1. I have found in Sicily and in Calabria cases of kala-azar in youths (13 to 18 years old) and among grown-up people (38 years old). Dr. Spagnolio has found the disease in a man 34 years old, and Dr. Tropeano in a girl 20 years old. 2. That the symptoms and the morbid anatomy correspond to those of Indian kala-azar. 3. That the researches of Longo (Clinica Pediatrica of the University of Catania) have shown that the leishmania of our kala-azar *lives in all those mediums in which develops Leishmania donovani.* 4. That the only difference between Indian leishmania and the Italian-Tunisian form lies in the fact that dogs cannot be infected with the first one. This has been admitted also by Nicolle in one of his letters, which I have published. Now what importance the experiment by Patton on dogs has in order to show the difference of the two parasites I have shown already in my note,[1] and I have repeated it on more than one occasion.

I, who have been occupied for three years in studying this problem of vital interest for South Italy, am of opinion that the two kinds of leishmania are (1) morphologically identical; (2) they develop in the same medium of culture; (3) they produce in monkeys the same infection; (4) they produce in man the same symptoms and the identical morbid anatomy. The clinical picture among us is more easily to be observed in children than in India. The disease shows also in Italy "epidemic recurrences" (spring).

The "Leishmania infantum Pianese" appears identical with "Leishmania infantum Nicolle"; according to my own studies and to other ones, Leishmania infantum and Leishmania donovani are synonymous.

The leishmania of the "*ponos*," a children's disease, which I have discovered to be nothing else than kala-azar, was shown in Greece to be the same as the leishmania which Cristomanos, Aravantinos, and others found in Greece among *grown-up people.* It is necessary to add that whilst Nicolle did not find cases in grown-up people in Tunisia, Dr. Tashin Bey found at Tripoli a young man aged 19 suffering from kala-azar. How can one write in my own cases, in those of Spagnolio, Cristomanos, Tashin, of a Leishmania infantum?—I am, Sir, yours faithfully,

Prof. Dr. UMBERTO GABBI,
Director of the Section of Tropical Diseases at the Medical Clinic of the University of Rome.

Rome, Jan. 26th, 1912.

To the Editor of THE LANCET.

SIR,—I notice in THE LANCET of Jan. 13th, p. 123, a letter by Captain J. Hay Burgess, I.M.S., in which he comments upon a paper of mine on the Leishmania in Mosquitoes, and I hope you will permit me to make the following brief reply, which will be given in greater detail in an article appearing in a future number of the *Annals of Tropical Medicine and Parasitology.*

It appears to me that Captain Burgess has either not read my paper carefully or he has not quite understood what I wished to express. I have stated elsewhere that I have read repeatedly the well-known researches of Captain W. S. Patton, but I cannot understand how Captain Burgess could possibly compare my researches on the A. maculipennis (1911)[2] and the later ones on some culicidæ, including S. fasciata (1911)[3] with those of Captain Patton on Anopheles stephensi and Culex fatigans. It must be remembered that A. stephensi is not found in Europe at all, and that C. fatigans is found only in Malta as regards European countries.

According to Captain Burgess it would appear natural that the same parasites found in A. stephensi should likewise be met with in A. maculipennis. It may well be that he has found flagellate and post(?) flagellate forms in C. fatigans, but this has no bearing on my researches. I have repeatedly and very clearly stated in my papers that I have made *numerous control experiments* in which I have *never* found *any* parasites such as were described from the insects found on the cultures. I have also stated that I have found, in smears made from mosquitoes which had been fed on cultures, small round or oval forms identical with those from individuals infected with kala-azar. Is it possible to mistake these small round oval forms for herpetomonas?

As regards the other experiments, it would have been better if Captain Burgess had more carefully read the last portion of my article published in THE LANCET, where I said that more sections of mosquitoes, and still further experiments with the non-flagellate parasites contained in the splenic juice, as well as animal experiments, &c., have to be made.

I should like to draw Captain Burgess's attention to the fact that it is possible to transmit the disease to animals by means of cultures of the parasite from the Mediterranean. My researches have only just commenced, and will be resumed as soon as possible; they had to be discontinued because of the scarcity of mosquitoes owing to the decrease in temperature. As regards the nomenclature of L. donovani and L. infantum, I cannot accept the statement that "Leishmania infantum and Leishmania donovani are not synonymous terms," since he does not give any plausible proof. Meanwhile I can affirm that the leishmania of the Mediterranean can be cultivated in Novy-MacNeal-Nicolle's medium as well as in citrated blood, that the morphology is the same, that the clinical picture and prognosis of the disease are the same, and also that during the last year a youth, 18 years of age, died in Rome from kala-azar, which has not been the first and only case.

It can, therefore, be easily understood that the problem is a complicated one which is evidently not to be solved with a few words, as Captain Burgess apparently desires.

I am, Sir, yours faithfully,

Liverpool, Feb. 15th, 1912. Professor G. FRANCHINI.

THE "RADICAL" OPERATION FOR MALIGNANT DISEASE OF THE TESTICLE.

To the Editor of THE LANCET.

SIR,—I have read with interest the paper in THE LANCET of Feb. 17th by Mr. H. Morriston Davies, entitled "Malignant Disease of the Testicle and the Treatment of it by Radical Operation." His summary of Nicholson's paper on the pathology of new growths of the testicle is excellent, and everyone will agree with him in his plea for the early recognition of this very grave form of malignant disease. The chief object of the paper, however, is to urge upon surgeons the adoption of a "radical operation" "unless the lumbar glands are extensively involved or there are evidences of metastases elsewhere"; indeed, his final point is that under these circumstances this "radical operation" "must be done." May I use your columns to ask Mr. Morriston Davies to give surgeons some firmer ground to rest upon than he has at present furnished? It is not enough to point to the known frequency of recurrence after simple castration, nor to show by the record of his own case that a certain form of extensive operation is feasible—"the patient returned home three weeks after the operation." What we need to be informed of is the *final result* of these "radical operations." Mr. Morriston Davies's own case was operated upon on April 5th, 1911—only ten months ago—and I infer that he is known to be free from all sign of recurrence *thus far*, but it would be a satisfaction to be distinctly told even this, and still more satisfactory to be told what is known of the other 13 cases of this operation to which he makes reference, the earliest of which, if cured of his disease, has now lived about seven years since the operation. I ask for details of 14—not 13—operations because, in spite of his footnote, I hardly

think Mr. Morriston Davies does my colleague Mr. J. Bland-Sutton justice in excluding his case from the list. The record of operations for malignant disease as mere surgical procedures is one thing; the right to attach the words "radical" or "ideal" to such operations is quite another. Surgeons know that Grégoire's operation can be done with safety by careful operators. What they want to know is the final (not immediate) result of this operation—its influence upon the course of the disease. Mr. Morriston Davies leaves us to suppose that all of the 13 (or 14) cases to which he refers justify his use of the word "radical" by having been permanently cured by the operation. Is this the fact? I ask for information, and by no means as a convinced opponent of this operation.

Mr. Morriston Davies refers to the general practice of surgeons in operating for malignant disease of the tongue and breast, and says: "There is no reason why the same radical treatment should not be adopted in cases of malignant disease of the testicle." In saying this, I think he has overlooked the difference in the usual clinical course of the disease in these different organs. Cancer of the tongue very often remains limited to the tongue and adjacent parts, and to the primary glands and the tissues around them, not only for months, but even throughout the whole course of the disease. Cancer of the breast, too, quickly infects the primary glands in the axilla, but in many cases does not spread further along the lymphatics for a long time. It is this great fact of the limitation of the disease to the area of operation that justifies, and explains the success of, our operations upon cancer of the tongue and breast. We cannot speak in similar words of malignant disease of the testicle; not only are the primary glands speedily infected and become the seat of very active growth, but the frequency and rapidity with which the disease spreads to the secondary glands, and further still, warn us not to rest our case for operation solely upon the results we obtain in operating for cancer of the tongue and breast.

However, I hope that Mr. Morriston Davies can reassure me on this point, and that, having recently looked up the records of all the published cases of this operation, he can tell us that a large proportion of them are living without sign of recurrence.—I am, Sir, yours faithfully,

ALFRED PEARCE GOULD.

Queen Anne-street, W., Feb. 19th, 1912.

THE VALUE OF SHORTCIRCUITING THE COLON FOR SEVERE CONSTIPATION.

To the Editor of THE LANCET.

SIR,—I should like to bring to the notice of the medical profession the very beneficial effects of Mr. Arbuthnot Lane's operation for the cure of chronic constipation as experienced by myself. Ever since an attack of typhoid fever when I was 18 (30 years ago) I have suffered from constipation of a very severe kind. During this period I have rarely had my bowels moved without aperients or enemata. Frequently I have gone a week without any action at all, and always the motion was hard and dry like sheep's dung. Along with this constipation I have suffered from dyspepsia, with its accompanying flatulence and acidity and general gastric discomfort. During the last four or five years my symptoms became much worse and it was with difficulty that I was able to continue my work.

In the autumn of 1908 I had a sudden attack of severe pain in the right hypochondrium which persisted for some days. I consulted a specialist who suspected that I had a duodenal ulcer. He called in a surgeon who opened the abdomen and found a large ulcer on the posterior wall of the duodenum. He did a gastro-enterostomy and I made a good recovery from the operation. For a time my symptoms were much relieved, but after six months the old symptoms of constipation, flatulence, &c., returned as badly as ever, and I had to give up work I became so ill. I consulted the same specialist again, who prescribed a raw, or practically raw, minced meat and minced chicken diet, with 30 c.c. of normal horse serum daily. This made me much worse, the pulse coming down to 44 and the temperature falling to 96° F.

I then lived for some months on a diet of milk, eggs, boiled fish, and toast. I was quite unable to digest anything else, but I got no better, so I consulted another surgeon who said he could do nothing without opening the abdomen again. This he did, and found the duodenal ulcer quite healed, but he found the appendix very much diseased, and he removed it. He told me he expected this had been the cause of my symptoms and that many cases got better after the removal of such an appendix. He also closed my pylorus. I again made a good recovery after the operation and for seven or eight months I did fairly well, but I always had a great deal of flatulence and often felt sick, which was a new symptom. I noticed the constipation was gradually coming back again, so I went to Harrogate and was instructed on the method of douching out the colon with large saline injections. This treatment relieved the constipation, but gave me so much pain, particularly in the region of the ascending colon, that I had to discontinue it.

I next tried dieting myself as recommended by Dr. A. F. Hertz in his book on "Constipation," eating porridge, wholemeal bread, with plenty of fruit and cream, and I persisted in this treatment for several months (December, 1910, to April, 1911). The constipation was certainly better, but I became weak and ill, and soon nervous symptoms developed which I had never had before. My thighs and calves were numb at times; at others I felt a feeling of pins and needles in the same parts. Towards the end of April, 1911, I completely broke down and was unable to do anything, so I consulted Mr. Lane, who sent me to Dr. A. C. Jordan to have the alimentary tract examined by means of the X rays. I was given a meal of 6 oz. of carbonate of bismuth, and this was carefully watched in its passage through the whole alimentary canal. The stomach was a little dilated but was vigorous in action, and the gastro-jejunostomy was working well. There was great delay in the passage of the bowel contents through the ileo-cæcal valve, and the terminal coil of the ileum appeared to be firmly adherent to the adjacent bone. There was also delay in the transverse colon, which hung down into the pelvis like a garland. The rectum was much elongated and in the form of a double S. On receiving Dr. Jordan's report Mr. Lane said another operation was necessary, so I placed myself entirely in his hands. He operated on me and found the last two inches of my ileum tightly bound down and very much constricted by a strong broad mesentery. He divided the ileum and put it directly into the rectum. The ileum showed very definite evidence of the chronicity of the obstruction. I made a very good recovery after the operation, and was able to return to work in ten weeks.

Now what benefits have I derived from the operation? 1. I now have a daily action of the bowels. At first there were several motions a day, but now things have become nearly normal. There is still a tendency to constipation, but this is easily remedied by fruit or some very mild aperient. It has been said that Mr. Lane's operation produces a state of chronic diarrhœa; I have not found it so. 2. The nervous symptoms mentioned before have completely disappeared and I sleep much better; formerly the insomnia I suffered from was very distressing. 3. My appetite has returned; indeed, it is almost too good, and I can eat an ordinary diet in moderation—a thing all dyspeptics will appreciate. 4. The principal benefit, however, is that I feel so well. I was an absolute physical wreck when I went to Mr. Lane in May; now I feel fitter and better than I have done for years.

I am, Sirs, yours faithfully,

F. P. BREMNER, M.B. Edin.

Lower Clapton-road, N.E., Feb. 20th, 1912.

PS.—I may say that both the surgeons who performed the previous operations were eminent men in the profession, so whatever they did was well done.

THE FATE OF THE APPENDIX AFTER ABSCESS FORMATION.

To the Editor of THE LANCET.

SIR,—Under this title an interesting paper by Mr. A. P. Dodds-Parker on the advantages of removal of the vermiform appendix in abscess cases appeared in THE LANCET of Feb. 10th, and has been followed by letters from Mr. Douglas Drew and Mr. H. J. Godwin in your issue of Feb. 17th. All the writers are agreed that in these cases the appendix is seldom destroyed by the disease or the suppuration that follows, and should be removed when the patient has recovered from a drainage operation. It is because the operation performed in the Royal Victoria Infirmary,

Newcastle-on-Tyne, where I was house surgeon, differs so materially from those advocated that I have ventured to offer a brief note as to the practice here.

A paper on "The Diagnosis and Treatment of Abscess in connexion with the Vermiform Appendix," by Professor Rutherford Morison, published 11 years ago in THE LANCET (Feb. 23rd, 1901), has been overlooked by your contributors, and as a large experience has confirmed the truth of the views he then expressed I should like to draw further attention to them. At the end of this paper he draws the following conclusions:—

> The diagnosis (of abscess) is based upon the history of an acute attack of appendicitis and the presence of a definite tender lump. The position of the appendix and the relations of the abscess may be foretold by a careful study of the tumour. (Every old house surgeon of Mr. Morison can fully bear this out, and the fact is insufficiently recognised, as it is most helpful in prognosis and treatment.) ..... Early operation is the proper treatment, and with few exceptions the vermiform appendix should be removed at the same time as the abscess is drained (pelvic cases form the chief exceptions to this rule).

A warning as to this is offered in the same paper in these words:—

> The operation should be done with the object of draining the abscess and removing the appendix, and, to do this safely, undoubtedly requires care and some practice. It also demands that the patient should not be too seriously ill to tolerate a fairly long operation; that skilled assistance should be available; and that the surroundings can be so adapted as to approach a hospital standard.

No detail of the operation then described has been altered, except that the catgut sutures are reinforced with silkworm-gut and that the amount of gauze used for drainage purposes has been diminished or altogether omitted. Later Mr. Morison[1] reports that he had operated on 110 consecutive cases on these lines without a death, and I recently collected statistics for him,[2] showing that 157 abscess cases had been operated upon in the Royal Victoria Infirmary without a death during the year 1910.

I am, Sir, yours faithfully,

Newcastle-on-Tyne, Feb. 18th, 1912. CHARLES F. M. SAINT.

KING EDWARD'S HOSPITAL FUND FOR LONDON AND THE EVELINA HOSPITAL.

To the Editor of THE LANCET.

SIR,—In justice to my committee I trust you will find space for this reply to the letter from the honorary secretaries of King Edward's Hospital Fund, which you have published in your issue of to-day. Their communication will, I fear, give the impression that my committee have deliberately departed from the uniform system of hospital accounts; this is not the case. It must be remembered that the legacy in question was absolutely unconditional, and *not* specified as being for the general purposes of the hospital. My committee, however, as a precaution sought legal advice, and ascertained that it would be a perfectly legitimate transaction to allocate it to the Samaritan fund. This legacy was then dealt with in accordance with a regulation of the King's Fund (No. 7 on p. 12 of their red book), which exactly applies to the case. This course has been approved by the hospital auditor who signed the accounts.

Paragraph 3 of the honorary secretaries' letter states that my committee have full power to apply the legacy to the general purposes of the hospital. Granted; but, having regard to the conditions just mentioned, they have also equal power to allocate it to any other object which is for the benefit of the hospital. If the committee of the King's Fund would be just in dealing with this matter, they must admit that it is not merely a question of hospital accounts, but also the strict interpretation of the wording of a will.

The letter from the honorary secretaries cannot fail to create the impression that my committee by their action wish to conceal the purposes for which the income of the Samaritan Fund is used. To this I must give a complete denial, and would point out that the authorities of the King's Fund know full well that the accounts of all special funds are published in our annual report, and are therefore open to the inspection and criticism, not only of the subscribers, but of anyone who may obtain a copy of the book.

In managing the affairs of this institution, which is the only large hospital for children in the whole of South London, my committee's only desire is to do, with the means at their disposal, the greatest amount of good for the sick poor, and by their straightforward policy hope to elicit the sympathy and support of the public.

Sincerely thanking you for your kindness and courtesy in publishing my other letter,

I am, Sir, yours faithfully,

D. MALCOLM SCOTT,
Feb. 17th, 1912. Chairman of the Committee of Management.

THE BIRTHPLACE OF LORD LISTER.

To the Editor of THE LANCET.

SIR,—I am writing in the room in which Lord Lister was born at Upton on April 5th, 1827. The house is, as you state in your obituary notice, now the Vicarage, and the Church of St. Peter is built upon a portion of the garden in which the great surgeon played as a boy. To the completion of this church Lord Lister himself contributed a few years ago, and we who worship in it think that it is a fitting home for a memorial to him, and that the best form that the memorial could take—of one who did more than any other man has done to alleviate suffering and to save human life—would be a rood screen with the figure of the Saviour of the World, and to this the character of the church is peculiarly adapted. We are all poor people here and cannot carry out our wish unaided. I therefore ask you of your courtesy to allow me to appeal through your columns for donations for this purpose—they could be given as a thankoffering in many cases for benefit received, as well as to perpetuate, on the scene of his birth, the memory of one who has placed the whole world under an obligation. I am, Sir, yours faithfully,

F. K. HODGKINSON, Vicar.

St. Peter's Vicarage, Upton, Essex, Feb. 16th, 1912.

PUBLIC HEALTH IN GRAND CANARY.

To the Editor of THE LANCET.

SIR,—Some report having appeared in the press regarding the prevalence of epidemic disease, I should be greatly obliged if you will give publicity to the fact that this island is, and has been, particularly free from infectious disease of any kind, the report being therefore quite without foundation. Visitors and invalids can enjoy the advantages of this delightful climate under as healthy conditions as exist anywhere. I am, Sir, yours faithfully,

W. M. M. JACKSON, M.D., D.P.H.

Las Palmas, Grand Canary, Feb. 10th, 1912.

FATALITIES FOLLOWING THE INTRAVENOUS INJECTION OF SALVARSAN.

To the Editor of THE LANCET.

SIR,—A correct appreciation of the value of salvarsan in syphilis, its efficacy in treatment, and the risks incurred, can only be attained by a careful consideration of all the aspects of the case. In THE LANCET of Jan. 20th (p. 152) you published an article by Mr. Willmott Evans in favour of salvarsan when employed with due care, and in your issue of Feb. 3rd (p. 283) you printed a valuable paper by Mr. Arthur Foerster, who has employed the drug widely, and who, with a recognition of its value, is also very certain that its use is by no means free from danger. In your issue of Jan. 20th (p. 153) Dr. J. H. Sequeira laid stress on the use of redistilled water in the preparation of the salvarsan for intravenous injection. It is certain that many precautions are needed to obtain the best results. You have referred[1] to fatal cases in which epileptiform convulsions and death occurred in young and strong patients after the intravenous injection of an ordinary dose of salvarsan. In those in which a necropsy was made hæmorrhagic encephalitis was found.

At the Académie de Médecine of Paris Professor Gaucher, who has succeeded Fournier as the leader of the French school of syphilography, referred recently to two fatal cases at the Saint-Louis Hospital. In one, a strong

[1] An address delivered at Halifax on Oct. 7th, 1903. See Northumberland and Durham Medical Journal for 1904, p. 263.
[2] Brit. Med. Jour., Oct. 28th, 1911; and THE LANCET, Dec. 16th, 1911, p. 1683.

[1] THE LANCET, Dec. 23rd, 1911, p. 1785.

country youth, in excellent health, contracted syphilis a month after going to Paris. A month later he came under the care of M. de Beurmann with an indurated chancre and double inguinal adenopathy. Examination of his organs revealed nothing abnormal and the urine did not contain albumin. On Sept. 18th an intravenous injection of 60 centigrammes of salvarsan was given with the usual aseptic precautions. There were no immediate symptoms, but after 15 minutes he was seized with vertigo and a feeling of heat. During the day he vomited abundantly, and in the evening his temperature was 100·7° F. On the following day he was quite well. On the 21st the injection was repeated under the same conditions as before. The same solution was used for the injection of another patient, who experienced no ill effects. At first the injection seemed to be well borne, but in the afternoon the patient was seized with vertigo, headache, and vomiting. The evening temperature was 101·5°. During the night he vomited again and complained of pain in the epigastrium. On the 23rd, while asleep, he uttered a cry like the bark of a dog and was seized with epileptiform convulsions, first tonic, then clonic. He bit his tongue and foamed at the mouth. At 4 P.M. he was comatose and made incoördinate movements. The pupils were dilated and immobile, and the face was pale and covered with sweat. The respiration was stertorous, the pulse 110, and the temperature 99·1°. At 4 A.M. on the 24th he died. At the necropsy the heart, great vessels, and lungs were found normal. So were the abdominal organs, except the kidneys, which were much enlarged, hard, congested, and of the colour of wine lees. The capsules were not adherent. Microscopic examination showed acute nephritis with epithelial degeneration and destruction of the tubules. The brain and meninges were normal to the naked eye. Professor Gaucher concluded that the patient died from uræmia, the result of arsenical poisoning. He considered salvarsan a dangerous drug, which should be used with the greatest care and reserved for cases in which mercury is badly borne or is without effect.

At a meeting of the Académie on Nov. 21st Professor Gaucher reported two more cases in which salvarsan had proved fatal. In one, communicated to him by Professor Oltramare, of Geneva, a robust man, aged 48 years, who had contracted syphilis 15 years before, desired an injection of salvarsan, although he had no symptoms. A complete examination revealed no sign of cardiac, renal, or nervous disease. On August 17th he was given an alkaline intravenous injection of 60 centigrammes of salvarsan. When seen again on the 19th he declared that he had well borne the injection and was quite well. On the 20th he complained of slight headache, and on the 21st he was found lying on the floor of his room. A medical man was summoned and found him unconscious, with convulsive movements, elevated temperature, and violaceous face. He remained in this state on the following day, and had several attacks of convulsions. He was covered with sweat and cyanosed. The pulse and respiration were rapid, the pupils were first dilated, then contracted, the temperature rose to 104 9°, and he died at midnight. The necropsy showed lepto-meningitis, scars on the ascending aorta, fatty degeneration of the heart, chronic bronchitis, and broncho-pneumonia of the lower lobes.

In another case, communicated by Dr. Caraven, of the Medical School of Amiens, a strong man, aged 21 years, who had just passed for the military service, came to hospital with a chancre. There were no signs of visceral disease and the urine did not contain albumin. On Oct. 11th an intravenous injection of 60 centigrammes of salvarsan was given and was well borne. On the 18th the injection was repeated and was equally well borne. But on the 20th the patient complained of headache, which was worse on the 21st. On the 22nd there were symptoms of meningitis—delirium, carphology, rigidity of the neck and upper limbs, and Kernig's sign. The respiration was stertorous and the pulse was 112. The pupils were slightly dilated, the eyes half open, and the conjunctivæ much congested. The face and nails were cyanosed and the patient was comatose. Lumbar puncture yielded cloudy, amber-coloured fluid. The urine contained 2 3 grammes of albumin per litre. In the afternoon he sweated profusely and there was Cheyne-Stokes respiration; the temperature rose to 104·2°. In the evening he died. The necropsy showed intense congestion of the brain and lungs. The kidneys were red and soft. The stomach presented a diffuse hæmorrhage.

It is now I think impossible to explain away all the fatalities by attributing them to errors of technique or use of this drug in unsuitable cases, as has been attempted by Ehrlich and his followers. To me it seems that there is incontrovertible evidence that the remedy is dangerous and may prove fatal to young strong patients. It is too soon, I consider, to estimate the position which will finally be given to salvarsan, but not too soon for emphasising its dangers, especially as they may present themselves to the general practitioner.

I am, Sir, yours faithfully,

M.D.

THE MEDICAL LIBRARY ASSOCIATION OF AMERICA.

To the Editor of THE LANCET.

SIR,—I have just read with interest the annotation on the Medical Library Association in THE LANCET of Jan. 13th. If you will permit me to correct an error, I believe conditions in this country are the same as in England—that is, we have some few large libraries and a number of small ones. In the large libraries it is "all give and no take," as the smaller libraries have nothing, or next to nothing, to contribute, while the larger libraries have hundreds of duplicates.

We have been endeavouring to develop an altruistic spirit in the medical libraries in this country, and, judging from the work in our Exchange, I think we are succeeding. I want to thank you for your kind words concerning our association and the *Bulletin*.

I am, Sir, yours faithfully,

JOHN RUHRÄH,
Treasurer.

Baltimore, Feb. 5th, 1912.

THE MEDICAL PROFESSION AND THE NATIONAL INSURANCE ACT.

To the Editor of THE LANCET.

SIR,—In the National Insurance Act, published by authority, at p. 135, Fourth Schedule, Part II., Additional Benefits, para. 1 runs as follows:—"Medical treatment and attendance for any persons dependent upon the labour of a member." This evidently includes wives and children who are not themselves workers. Does it apply only to relatives of members of approved societies? And what is the scale of remuneration for such medical treatment and attendance? Is it left for the Insurance Commissioners to arrange? Can any of your readers explain?

I am, Sir, yours faithfully,

W. J LE GRAND, M.D. R.U.I.

Blackwell, near Alfreton, Feb. 14th, 1912.

To the Editor of THE LANCET.

SIR,—May I be allowed to refer to a section of the National Insurance Act to which nobody seems to have given much attention, but which is of very great importance to all medical men practising in seaport towns? The section has, I think, never been referred to in the correspondence in your columns; it does not seem to have been brought up before the Council of the British Medical Association, for it is nowhere referred to in their recently issued "Report"; it has apparently escaped the notice of the eminent counsel consulted by the *Practitioner;* it is not noticed in the "Reform Committee's" "proposal for an amended Act," and in the "tabulated list of clauses" published by you in your number of Feb. 10th the number of the section is divorced from its contents, yet it is the only section of the Act which gives a direct negative to one of the "six cardinal points."

The section referred to is Section 48, "special provisions for the mercantile marine," and the especially interesting subsections are:—

(4) The Board of Trade shall ..... cause a society to be formed, t be called the Seamen's National Insurance Society, of which any masters, seamen, and apprentices to the sea service and the sea fishing service who are employed within the meaning of this ..... Act shall be entitled to become members.

(5) The affairs of the S.N.I.S. shall be managed by a committee ..... comprising representatives of the Board of Trade, of shipowners, and of members of the society in equal proportions, and the society shall, notwithstanding anything in this ..... Act, become an approved society.

(12) Members of the S.N.I S. shall be deemed to reside in England, and the *medical benefit* of such *members* shall be *administered* by *the*

society instead of by the Insurance Committee ; ..... but nothing in this provision shall prevent the society agreeing with Insurance Committees for the administration of those benefits by the Committee in relation to *individual* members of the society.

That this new society will become an extremely rich and therefore powerful and attractive one is rendered probable by the fact that, whilst the calls upon it for benefits will be small owing, under 48 (1), to neither sickness nor disablement benefit being paid to its members in respect of any period during which the owner of the ship is, under the Merchant Shipping Act, 1894, liable to provide medicine, attendance, and maintenance, at the same time, by 48 (6), the whole of the contributions paid by employers in respect of masters, seamen, and apprentices who are neither domiciled nor have a place of residence in the United Kingdom will be credited to the society. And yet the medical benefit of this powerful society is to be entirely under lay control, and not a single representative of the medical profession is to be allowed to have a place on the committee of management.

Can anyone say in face of the direct prohibition in this section that it is still possible to obtain the six points by arrangement with the Insurance Committees?

I am, Sir, yours faithfully,

Ramsgate, Feb. 17th, 1912. FRANK MILTON.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Late Lord Lister.

IT was appropriate and right that a religious memorial service should be held in Edinburgh simultaneously with the service which was held in Westminster Abbey on the day of the burial of Lord Lister. The service was held in the ancient church of St. Giles ; it was attended by the Lord Provost and magistrates of the city in their official robes ; by the University, led by the Principal, Sir William Turner ; by the Royal College of Physicians, represented by the Council and many of the Fellows ; by the Royal College of Surgeons, represented by its Council and a large number of its Fellows; and by members of the profession belonging to neither college. The students were present in considerable numbers, and were officially represented by members of the Students' Representative Council. There were also present a large number of non-medical members of the community. The service was conducted by the Rev. Dr. Wallace Williamson, assisted by one of the University professors from the Faculty of Divinity, and one from the New College. The service was short, simple, and dignified. The anthem selected was the passage beginning "What are these that are arrayed in white robes," and ending with the passage, "And God shall wipe away all tears from their eyes," which was rendered with great beauty by the choir. The address was delivered by the Rev. Dr. Wallace Williamson, and showed a wide and deep understanding and appreciation of the great work Lister had done, and an intimate knowledge of what Lister was as a man. He concluded an address worthy of the occasion as follows: "The whole world stands debtor to Joseph Lister to-day. The whole world offers grateful homage to his memory. It is in this spirit we meet to-day. In humble gratitude for a whole life devoted to the highest and purest aims, for the splendour of his example, for his courage and tenderness, as well as for his undying gift to humanity, we bid him a proud farewell."

Edinburgh and the National Insurance Act.

If Mr. Lloyd George had for his purpose in the London Opera House speech to stiffen the backs of the profession in Edinburgh, and to make the counsel of moderate men, who are looking further ahead than next July, of no avail he is to be congratulated. Even supporters of the present Government have been rendered actively hostile. The Chancellor of the Exchequer has been an unspeakable trouble to his political friends in medicine, many of whom in their loyalty, first to medicine and secondly to their party, have been greatly embarrassed. Edinburgh has this week declared against the Act again, and at the divisional meeting of the British Medical Association selected three new representatives to the Representative meeting pledged to vote against the Act, and to vote for the removal of Dr. Maclean from the chairmanship of that body. I understand that the effect of the Chancellor's speech has not been so marked everywhere in Scotland as it has been in the Edinburgh district. Meanwhile, the election of representatives from the insurance areas to the Scottish Medical Insurance Council has been going on quietly and steadily. The Edinburgh and Leith Practitioners' Association has passed a vote of thanks to the medical corporations for the part they took in forming that council. It is expected that the Scottish Insurance Council will meet early in March.

Medical Officership of Stirlingshire.

A special meeting of the Stirling county council was held in Stirling last week for the purpose of considering the question of the appointment of a medical officer of health for Stirlingshire in the room of Dr. J. C. McVail, who was recently appointed Deputy Chairman of the Scottish Commission under the National Insurance Act. The council considered a recommendation from the public health committee to the effect that the present arrangement of a joint medical officer for the two counties of Stirling and Dumbarton, which had subsisted since 1891, should be continued, but on a division this recommendation was defeated, and it was agreed that a separate medical officer should be appointed for Stirlingshire. It was ultimately decided that the salary of the new medical officer should be £500 per annum, with travelling expenses and clerical assistance. The public health committee was empowered to make the appointment, suggested stipulations to the effect that the applicants should be able to make bacteriological examinations and that they should reside in the county of Stirling being disapproved.

Coöperation of Trained Nurses, Glasgow.

The nineteenth annual report of the Glasgow and West of Scotland Coöperation of Trained Nurses has just been issued. It forms very interesting reading, and proves the immense benefit that such an institution confers upon medical men, upon the general public, and upon the nurses themselves. The number of nurses on the roll is 185, and during the year 2096 cases were attended by them. The amount earned by the nurses during the year was £12,605, and since the establishment of the coöperation in 1894 the amount earned is £145,060 from attendance on 24,271 cases. The principle on which the institution is worked is that at the termination of a case the nurse collects the fee and pays to the lady superintendent a percentage thereof, which is placed to the credit of a common fund out of which the yearly working expenses of the coöperation are defrayed. A sick fund established in connexion with the association has a capital of £4301. All nurses (with the exception of a few who are already members of the Royal National Fund) contribute £1 per annum. These contributions, along with the income from investments and subscriptions from friends, have enabled the necessary payments to be made and a balance carried forward. The standard of qualifications for nurses has been gradually raised, while regular and continuous employment at remunerative rates, with the benefit of the sick fund, is practically guaranteed to them.

Gift of £1000 to Dundee Infirmary.

The Royal Infirmary, Dundee, has received from the widow and family of Mr. J. J. Weinberg the sum of £1000 towards the out-door relief funds of the institution, and in memory of Mr. Weinberg, who was for many years identified with the management.

Presentation to Dr. W. Brown of Braemar.

On the evening of Feb. 14th Dr. William Brown, who is leaving Braemar to take up practice in Aberdeen, was met by a large number of friends, and presented with a Barlock typewriter and a silver tea service, while his sister, Miss Brown, received a gold bangle. These gifts mark the appreciation of the respect and esteem in which Dr. Brown is held, and of the good services he has rendered to Braemar during his eight years' residence there.

Feb. 19th.

DONATIONS AND BEQUESTS.—By the will of the late Surgeon-General Sir John A. Woolfryes the St. George's Hospital, the Royal Home and Hospital for Incurables, Putney, and the British Medical Benevolent Fund will each receive £500.—The Goldsmiths' Company have sent £1000 to St. Bartholomew's Hospital for the general funds of that institution.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Royal Hospital for Incurables and Provision for Consumptives.

THE campaign against the extension of the Royal Hospital for Incurables by the addition of a pavilion for tuberculous patients is being carried on with vigour. At a public meeting held in Rathmines town-hall last week resolutions were carried protesting against the proposed action of the hospital authorities. It has been pointed out by a well-known Dublin surgeon that "all modern medical knowledge points to the fact that no case of consumption should be called incurable." A number of governors of the hospital have forwarded a memorial to the managing committee, praying the committee to reconsider its decision. The memorial might have carried more weight had it not followed closely on an unsuccessful attempt by the objecting governors to force their views on the managing committee at the recent election of five members of that committee. The question of the enlargement was made a test question, and the objectors failed to win a single place on the committee. If by any chance the committee is prevented from carrying out its scheme a very serious problem is raised. The Royal Hospital for Incurables is situated in an open suburb, but the workhouse hospitals, which contain many scores, if not hundreds, of tuberculous patients, are situated in densely crowded districts. A home for the dying, with consumptive patients, is in a crowded and poor district. The two fever hospitals, and the fever wings of the various city hospitals, are situated without exception in populous districts. If there is any danger of air-borne infection, the danger from these institutions must be infinitely greater than that from the Royal Hospital for Incurables. Nevertheless, many of the people officially connected with one or other of these institutions are among the loudest in their criticism of the Royal Hospital for Incurables.

Deaths of Children by Burning.

During the present winter very many deaths of children by burning have occurred. A few weeks ago the board of the Meath Hospital drew the attention of the public to the large number of fatal cases which had been attended in the hospital. It would appear as if the health authorities did not take any steps to enforce the provisions of the Children Act. At a recent meeting of the Dublin Sanitary Association a resolution was passed in which the council call the attention of the coroner, the sanitary authorities, and the public in general to the fifteenth section of the Children Act, 1908 (8 Edw. VII., ch. 67), which imposes substantial penalties on the guardians of children of tender years for exposing such children to risk of burning.

High Death-rate in Belfast.

Belfast is at present in the grip of a severe epidemic of influenza and of whooping-cough, with the result that the death-rate for the week ending Feb. 10th was from all causes 41·7, and from the principal zymotic diseases 2·7. This appalling mortality places Belfast at the height of all the towns of the United Kingdom, and the rate is nearly double that of the average of the English towns. The weather is mild, but pneumonia and chest ailments are very prevalent, the death-rate from these complaints alone being 21·7 per 1000. During the week ending Feb. 10th 15 deaths were due to whooping-cough, 73 to pneumonia, and 67 to diseases of the respiratory organs. During the week ending Feb. 15th 146 children under five years of age died, which was equal to a rate of 19·4 per 1000 of the whole population. Of these deaths, 108 were attributed to chest affections, whereas the average number of deaths of children under five years of age was 38, or 5·1 per 1000. Of the present epidemic of influenza, the marked features are throat, ear, and chest complications, and especially high temperatures among children.

Ulster Medical Society.

At the sixth meeting of the Ulster Medical Society for this session, held in the Medical Institute, Belfast, on Feb. 15th, the President, Dr. H. L. McKisack, being in the chair, Sir John W. Byers showed an old midwifery book, published in 1663, containing "The Compleat Midwife," by the celebrated Madam Louise Bourgioes, who attended Mary de Medici, wife of Henry IV.; "A Full Supply" of most useful and admirable secrets, by T. Chamberlain, M.P.; and "Rare Secrets in Midwifery," by Sir Theodore Mayern, who was physician to Charles I. He gave an account of each of these writers. Mr. P. T. Crymble showed a most interesting series of Roentgen ray photographs of the stomach after a meal with bismuth had been taken, to illustrate the action and position of that organ during digestion, and he also exhibited a number of stomachs prepared by formalin injection. In the discussion that followed Dr. W. Calwell, Professor J. Symington, Dr. A. Fullerton, Professor T. H. Milroy, Dr. S. T. Irwin, and Sir John Byers took part.

The Vice-Regal Milk Commission.

This Commission spent five days of last week in Belfast in interrogating a large number of witnesses, principally official. Their inquiries conveyed the impression that it was a pity the *personnel* of the Commission had not been strengthened by the presence of a pathologist, as well as by someone who had a thorough practical knowledge of the modern production, method of sale, and distribution of milk. Dr. W. St. C. Symmers, professor of pathology in the Queen's University of Belfast, in the course of his examination said he was not in favour of milk being subject to the process of pasteurisation. He thought the food properties of the milk were by this process undoubtedly impaired—why, he did not know. He had spoken to men who had large experience in the treatment of children, but not one held that pasteurised milk was as good as raw milk. He was still less in favour of sterilisation. To the great amusement of those present a lady member of the Commission then proceeded to point out to the professor, as though he were a nurse or a first-year medical student, the special advantages of pasteurisation, with the idea of showing him the error of his ways and the scantiness of his knowledge, the lady herself being apparently unaware that the Belfast corporation several years ago declined the gift of a pasteurising plant from Mr. Strauss. Another member of the Commission inquiring on the subject of immunisation, asked if the fact of people being supplied with milk containing an undiscovered tuberculous fraction did not tend to set up immunity from tuberculosis; to which Professor Symmers replied that that was certainly an extraordinary theory. They could not make all-round experiments that might be exceedingly dangerous. Were they to inoculate a child with anthrax it would in all probability mean the death of the child. He certainly would not father a view that would justify the selling of tuberculous milk to the public. It will be interesting to read—after a time—the conclusions and recommendations of a milk commission of which some of the members seem to regard "pasteurisation" as the solution of the milk problem, while others consider the taking of milk containing a few living tubercle bacilli is likely to set up immunity from tuberculosis.

The Insurance Act.

At a meeting of the Belfast Trades Council on Feb. 17th the following resolution was carried:—

That the secretary of the Belfast and District Trades and Labour Council be instructed to write the leaders of the different political parties and Ulster M.P.'s to urge them to bring pressure on the Government to pass a one-clause Act restoring the medical benefits to Ireland, as the absence of such benefits will severely handicap approved societies in Ireland, it being impossible for them to provide any safeguard against malingering and other abuses owing to there being no control over the doctor. We are also of opinion that the medical benefits are the most valuable benefits in the Insurance Act, and owing to its higher death-rate these are more needed in Ireland than any other part of the kingdom.

Feb. 20th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Death of Lord Lister.

THE great loss that British science has sustained in the person of Lord Lister has been felt in all countries. In France the Academy of Medicine suspended its session in sign of mourning, and the Academy of Sciences directed its President, M. Lippmann, to represent it at the funeral ceremony. Arrangements were also made for him to be accompanied by M. Chauveau (professor at the Museum), M. Dastre (professor at the Sorbonne), and M. Roux (director of the Institut Pasteur.)

Transmissible Diseases in Paris during 1911.

While a great number of cases of transmissible disease were reported in Paris during 1911, the figures are not at all surprising if its population is taken into account. The following is the official total as issued by the Prefecture of Police: Typhoid fever, 2175; variola and varioloid, 93; scarlet fever, 3565; measles, 11,987; diphtheria and croup, 3043; cholera and choleriform diseases, 32; ophthalmia neonatorum, 179; cerebro-spinal meningitis, 94. In the suburbs the figures are as follows: Typhoid fever, 1660; variola and varioloid, 23; scarlet fever, 1523; measles, 2349; diphtheria and croup, 1475; cholera and choleriform diseases, 8; ophthalmia neonatorum, 63; cerebro-spinal meningitis, 49.

The Isolation of Infectious Diseases in Schools.

The *Journal Officiel* has published a notice laying down the duration of isolation to be practised for pupils at public schools of all kinds who may be attacked with infectious disease, and the conditions that may determine this duration both for the patients and for their brothers and sisters. Pupils with diphtheria may return to school 30 days after a clinical cure, as certified to by a medical man. This delay may be lessened if, after two cultures made at eight hours' interval, the bacteriological examination is negative. In small-pox, 40 days after the beginning of the disease, readmission can be allowed on presentation of a medical certificate stating that there are no crusts or scales and that the pupil has taken a bath. In scarlet fever, the same measures as in small-pox. In measles, after 16 days. In mumps, 21 days. In whooping-cough, 30 days after absolute disappearance of spasmodic accesses, certified to by a medical man. In rubeola, 16 days. In typhoid and paratyphoid fevers, 28 days after cure, as certified by a medical man. In dysentery, 28 days. In cerebro-spinal meningitis, 40 days after a clinical cure medically certified. In poliomyelitis, 30 days after the beginning of the disease. In tinea and trachoma, when cured. If the patient has not been isolated his brothers and sisters will be allowed to return at the same time as himself provided they have escaped attack. If the patient has been isolated, the readmission of the brothers and sisters will take place, with certain exceptions, after a delay corresponding to the incubation period of the disease plus two days.

Evils of High Heels.

At the Société de Médecine de Paris, on Jan. 27th, M. Dagron showed that high heels can not only give rise to pain and contracture, but can set up a true inflammation of the tendons of the postero-inferior part of the calf. This affection may simulate a deep varicosis or even a cold abscess calling for special treatment, while all that is really required is rest and re-education in walking without high heels.

"Study Travels."

The "study-travel" of the Association Internationale de Perfectionnement Scientifique, an organisation which has the support of the French Government, will take place from August 10th to Sept. 6th in the Balkan countries, Turkey, and Greece. Aix-les-Bains is the place of assembly. The itinerary will take in Venice, Trieste, Agram, Sofia, Constantinople, Mitylene, Smyrna, Athens, Eleusis, Olympia, and Corfu, the final meeting to be held at Evian.

The Faculty of Medicine of Paris.

By a decree rendered Jan. 31st, on the recommendation of the Minister of Public Instruction and the Superior Council of Public Instruction, it is declared that the organisation of the practical school of the Faculty of Medicine of the University of Paris and the regulations relating to the nomination and to the attributions of its *personnel* are determined by ministerial decrees made in the permanent section of the Superior Council of Public Instruction after consultation with the Council of the Faculty, and that all contrary dispositions of preceding regulations are, and remain, repealed. On the other hand, the Minister of Public Instruction has addressed to the Vice-Rector of the Academy of Paris a circular relative to the reopening of the Faculty of Medicine. This will be reopened for students of medicine of the first and second years on March 1st next. According to the proposals addressed by the Vice-Rector, together with the Dean of the Faculty of Medicine, the Minister has decided that second-year students shall be called on to take up practical work at dissection from March 1st, and to continue it during March and April. During this period anatomical demonstrations will be made three times a week by an *agrégé* of the Faculty. The time of the first examination will be, as an exceptional measure, postponed for them from March to May, the date to be fixed by the Dean. For first-year's students practical work at anatomy will begin in 1912–13, not on Nov. 3rd, but on Oct. 1st, and if necessary it will be continued beyond Feb. 28th following. The Minister hopes that circumstances will permit these students to take the first examination at the ordinary date in 1913. Students of this class will be allowed to enter for the posts of residency at the hospitals at the usual dates conditional upon being properly "signed up."

The Medical Men's Art Salon.

The third medical salon will be open from March 12th to 24th next in Paris. As on former occasions, all professors, practitioners, internes, and students are permitted to exhibit paintings, sculpture, water-colours, engravings, pastels, designs, and decorative art. This year a section will be devoted to medals and *objets d'art* bearing some relation to medicine.

Feb. 20th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Dissatisfaction among Medical Students in the University of Breslau.

ANATOMICAL study in the University of Breslau has of late been interfered with by the existence of very strained relations between the students and the professor of anatomy. The students some time ago complained to the Minister of Public Instruction concerning certain proceedings in the State examinations and their personal treatment by the professor. The Minister succeeded in pacifying the students for a time, but they have again become highly incensed on account of a line of action which the professor has now taken. He had the doors of his lecture room closed at the beginning of his lectures, so that late comers could not enter, and he refused to give certificates to those who had complained, so that they could not apply for admission to the State examination. These restrictions led the students to adopt a course not unusual in Russia, but hitherto unknown in Germany, the result being that they boycotted the professor so that when he intended to deliver a lecture on topographical anatomy he found the amphitheatre empty. The Dean of the Medical Faculty tried to conciliate both parties, and after the professor had explained his motives at a meeting of the students the boycott was stopped on condition that the professor resigned his position as a member of the examination board. He has now reached an advanced age and will probably soon resign his University appointment altogether, because his behaviour has created some prejudice against the University of Breslau, and the number of medical students has considerably decreased there.

The Relation of the Wassermann Reaction to Lead Poisoning.

Some recent observers using the Wassermann reaction have obtained positive results in certain cases of lead poisoning, a circumstance which if true would have certainly an important bearing on the value of this reaction from a clinical and theoretical point of view. In a recent number of the *Deutsche Medizinische Wochenschrift* Dr. Hilgermann, medical officer of the city of Coblenz in Rhenish Prussia and chief of the public laboratory there, published a series of observations made by him on workmen of the extensive lead and silver smelting works at Braubach, in the neighbourhood of Coblenz. He examined 34 cases of acute, subacute, and chronic lead poisoning, with typical symptoms, including anæmia, pain in the joints, polyneuritis, paresis of the radial nerves, and Bright's disease. A typical line of blue was always present in the gums. The result was that the Wassermann reaction was negative in every case, and Dr. Hilgermann concluded that this reaction must be regarded as characteristic of the presence of syphilis. It was probable that in the cases of lead poisoning examined by other medical men who had found a positive reaction the patients had been syphilitic without having been aware of their disease, a fact not very uncommon among the working population. Moreover, the modification of the reaction

devised by Dr. Stern, and frequently used by various medical men, might be regarded as not absolutely reliable; at any rate, Dr. Hilgermann, working strictly in accordance with Professor Wassermann's directions, has come to contrary results.

Medical Certificates for Motorists.

The Secretary of State for the Home Department has recently issued new regulations concerning the medical examination of candidates for a certificate as motorists. A sound body and normal powers of hearing and seeing are indispensable; the right arm and leg must be freely moveable; in the case of contractions or loss of single fingers it must be ascertained whether the motorist is able to manage the steering wheel with one hand. A minimum visual power of two-thirds in one eye and of one-third in the other is required. Night-blindness, diminution of the field of vision, paresis of the muscles of the eye, and well-marked strabismus render the applicant unfit for the certificate. Whispering voice must be heard at a distance of at least 3 metres. In the case of persons suffering from tabes, diabetes, or diseases of the chest, the abdominal organs, the great vessels, or the kidneys, the decision will depend on the circumstances of each individual case. When general paralysis is suspected the examination must be repeated after a certain time. Well-marked neurasthenia, giddiness, insanity, and epilepsy, of course, make a person absolutely unfit for motor driving.

Statistical Investigation on Venereal Diseases.

A statistical investigation concerning venereal diseases was lately made in the Duchy of Brunswick, one of the smaller states of the German Empire, with a population of about half a million. A similar investigation had been carried out in the kingdom of Prussia about ten years ago, but whilst in Prussia it occupied only one day, April 30th, it was extended in Brunswick over half a year. Obviously the latter method, although not practicable for a large country and for many thousands of medical men, but rather easy in a small country, gives more reliable results; and, in fact, the number of patients recorded was greater in Brunswick than in Prussia. The investigation included syphilis, gonorrhœa, soft ulcers, and condyloma. The results were contained in 842 cards returned to the Statistical Office of Brunswick from the medical men and the hospitals of the country. According to the *Deutsche Medizinische Wochenschrift*, the statistical returns show (1) that venereal diseases are found in an alarming number among every class of the population; and (2) that they are relatively more numerous in the towns than in the country, and relatively highest in the only large town of the duchy, the city of Brunswick. In the country districts syphilis is just as frequent as gonorrhœa. Gonorrhœa predominates in the male sex and syphilis in the female sex. The number of married patients is considerable. Prostitution has an essential influence on the spread of venereal diseases. Of the male patients, 35·4 per cent. were workmen, and 22·3 per cent. were tradespeople, the remainder including State officials, soldiers, members of the higher professions, &c. In the latter class syphilis is especially prevalent, while in the other two classes gonorrhœa predominates. Of each 10,000 of the population, 39·1 in the city of Brunswick, 10·8 in the other towns, and 3·6 in the country were venereal sufferers. Obviously venereal diseases are more easily spread the more dense the population. The greatest number of syphilitic patients was recorded for women in the age between 20 and 25 years, and in men in the age between 25 and 30 years.

Club Practice in Germany.

The Supreme Court of Appeal of the German Empire has now pronounced its decision in a conflict which broke out nearly seven years ago between eight sick club doctors and the club authorities. In September, 1905, the doctors of the town sick club of Remscheid resigned their duties in a body, and the reasons given for this step afford an apt illustration of the unfortunate position in which many club doctors in Germany are placed owing to the authority vested in the committees managing these bodies. The doctors based their step on the fact that the actions of the committee placed them in a position derogatory to their professional dignity, and therefore made it incompatible for them to continue their duties. The committee arbitrarily imposed fines, or, indeed, made deductions from their remuneration for alleged infringements of certain rules drawn up by the committee. Further, all prescriptions were submitted to a rigorous revision with a view of controlling the cost of treatment, and the doctors were compelled to prescribe as cheaply as possible, the rules drawn up for prescribing being such that in many cases the enforced cheap method of treatment ran counter to the interests of the patients. On the other hand, when asked to give certificates entitling the members of the club to draw pensions provided by the Imperial funds they were expected to make statements in favour of the applicant's claims. The sick club authorities asserted that here the action of the doctors had caused an extra expenditure of £5250 to the club, and claimed the payment of this amount from the doctors. In the first instance the doctors won, the court expressing the opinion, *inter alia*, that the fact that they had given up an assured position under the club for an uncertain future was proof of the existence of conditions which rendered a continuance of their duties, in the circumstances, practically impossible. The club committee appealed against this judgment, and in the higher court won the case, the decision being principally based on the view that the doctors should have awaited the decision of the arbitration board provided by the rules of the club for dealing with disputes between the medical attendants and the committee. The matter was then brought before the Reichsgericht in Leipsic, which has now referred the case for retrial in the lower court, this decision being based on the view that the evidence abundantly proved the existence of unsatisfactory conditions in the management of the club.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

New Views as to the Pathology and Treatment of Tuberculosis.

IN the year 1909, on the occasion of the International Medical Congress held at Budapest, Dr. Joseph Hollós, pathologist to the County Hospital in Szeged, wrote a book entitled "The Tuberculous Intoxications." He read portions of it at the meeting and delivered an address on the subject, but neither his book nor his address made any great impression. His views were so heterodox that most of his hearers turned deaf ears to his arguments. At the same time he published in a German periodical an article which attracted the attention of Dr. Poncet, a well-known professor in the University of Lyons. Dr. Poncet entered into communication with Dr. Hollós and persuaded him to have a French translation of his book published in Paris. Dr. Poncet himself wrote a preface to this work, and has eulogised it in several addresses delivered by him before the Paris Academy of Medicine. Other speakers have discussed it at meetings of the Paris Medical Society and in other scientific assemblies. The interest taken by leading French medical men in the work of Dr. Hollós was further shown by the fact that a year ago he received an official instruction from the Paris Academy of Medicine to compete with his book for the valuable Audiffred prize.

On account of the favourable reception which was given to Dr. Hollós by the French medical profession the Hungarian Minister of Public Education sent him at the expense of the State to study in France and Germany for half a year, and during this time he wrote another book entitled "Therapie der latenten und larvierten Tuberculose" ("The Treatment of Latent and Masked Tuberculosis"). This work has been published by T. F. Bergmann in Wiesbaden, with a preface written by Professor Carl Spengler, of Davos in Switzerland. The principal points of it are as follows. The latent tuberculous foci of the organism create in it a certain degree of immunity, in consequence of which the organism develops a high quality of sensitivity against its own toxins. As a result of this sensitivity to the toxins the organism reacts with various symptoms, which manifest themselves by certain nervous phenomena, by disorders of metabolism, by anæmia, and in particular by chronic headache, frequent fainting, loss of appetite, cardialgia, increased or decreased secretion of the gastric fluid, habitual constipation, diarrhœa, abnormalities of sleeping and dreaming, and sensations of great fatigue, particularly in the morning. The patients also suffer from decreased mental and bodily activity, from various

nervous and cardiac troubles, chiefly palpitation and tachycardia, from night sweats, from many different disorders of menstruation, and from rheumatic pains in the joints. The greater the degree of immunity the more pronounced are these symptoms, one or the other of which (and sometimes all of them) may last for years. Such cases are for the most part erroneously diagnosed as anæmia, or neurasthenia, or hysteria, or various neuroses.

These examples of the latent stage of tuberculosis respond very well to antituberculous treatment, and they mostly end in complete recovery. If the immunity, and together with it the sensitivity to the toxins, diminishes from any cause whatever, then also these symptoms cease spontaneously, but the disease progresses into manifest pulmonary tuberculosis, and in this way the above-mentioned symptoms very often form the first stage of that disease. If the pulmonary tuberculosis presents itself as such in the first instance and is neither preceded nor accompanied by symptoms indicative of toxic action, then from this it may be concluded that the immunity was insufficient and that the prognosis is bad. Dr. Hollós also believes that goitre is in the majority of cases of tuberculous origin, the toxins of the latent tuberculosis producing the hypertrophy and abnormal function of the thyroid gland.

In numerous cases the administration of immune bodies resulted in entire and final recovery. Dr. Hollós has used this specific method of treatment in more than a thousand cases and has made careful notes of all of them. The patients under his care were without exception treated with Spengler's serums—namely, the smaller half of them with tuberculin (on the ground of the dualistic therapy) and the larger half with the "Tuberkulose Immun-Körper."[1] It is noteworthy that Dr. Hollós succeeded in either intentionally provoking all the above enumerated symptoms or in increasing their severity when they already existed simply by the use of artificial toxins, and at the same time in stopping them when he so desired. Of the patients treated with the specific method some have wholly recovered, but the greater part relapsed after a period varying from three to six months and even longer. It has, however, to be remarked that the relapse was not complete in all the cases, because there were some instances wherein the patients originally suffered from three or four symptoms, and when they had a relapse after six months they now suffered from only one or two symptoms. The advent of the relapse is an indication that specific treatment must be resumed. According to Dr. Hollós, the Immun-Körper treatment produces results far surpassing those obtained with tuberculin and climatic treatment. The key to success is the proper individualisation of the cases, and for this purpose it is necessary to pay the most careful attention to the toxic symptoms.

I have no knowledge how far in England either the theories or the practice enunciated above have received trial or obtained support.

Feb. 13th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

A Women's Medical Service for India.

As the *Times* has recently published a series of letters, mainly from women doctors, pointing out the urgent need of adequate provision for the medical necessities of Indian women, and in an article recently published urges the establishment of a female side of the Indian Medical Service, it may be interesting to give the readers of THE LANCET some idea of how this proposal is received in India. The *Civil and Military Gazette* devotes a leading article to the subject which may be taken to represent lay opinion on the matter. It is pointed out that it is hardly necessary to labour the urgency of the need, or the utter inadequacy of existing provisions for medical aid to women in this country. There are about 150,000,000 women in India, and at least two-thirds of these have the most profound objection to be treated by male doctors. To meet the needs of these millions there are about 400 fully qualified medical women in India, about half of whom are missionaries, and the remainder mostly connected with philanthropic or charitable institutions.

The problem of lessening the burden of sickness and suffering amongst Indian women has never yet been seriously faced, and it cannot be solved either by the private enterprise of medical women or by any unofficial and philanthropic agencies such as the Dufferin Fund. The Dufferin Fund and the mission hospitals alike do excellent work up to the limit of their capacity, but they cannot supply more than the smallest fraction of the need. Even the Dufferin Fund, which has received assistance and moral support from Government, lives up to the limit of its resources, and it was acknowledged in the last annual report that the pay and prospects offered to women doctors are alike inadequate, but cannot in present circumstances be increased. Moreover, the Dufferin Fund employs, not the thousands of women doctors who are needed, but 47 women doctors of the grade, 92 assistant surgeons, and 670 hospital assistants. Under the existing rules of the Fund the pay is small and stationary, there is no provision for pension, the tenure of appointments is precarious, and even furlough is not in some cases guaranteed. Such precarious conditions are incompatible with good work, and the hardships are not minimised by the fact that working side by side with the women doctors are Englishmen with the same professional qualifications who enjoy the protection of a recognised Government service, with assured work, adequate and progressive pay, and furlough and pension guaranteed. If the Dufferin Fund with all the prestige attaching to it cannot provide its women doctors with a career that satisfies, it may be taken for granted that the task is beyond the resources of unofficial agency.

In any case, there is no possibility that any such agency could create an organisation so widespread as to meet the need of India. The creation of an adequate State service would be difficult, and it would be costly, though it could be inaugurated on a modest scale and developed as funds became available. Twenty-five years ago, or even less, a proposal to establish such a service might have been received with sullen objections if not with open and vigorous opposition. But the patient work of the Dufferin and mission hospitals has to a very large extent broken down Oriental prejudices and developed widespread appreciation of the benefits of Western medical science. In practically all the Dufferin Fund reports we read of the demand for increased accommodation, and especially for more *purdah* wards, for the women of India have learned to appreciate the value of skilled nursing and medical treatment by members of their own sex. It is believed that the initiation by Government of a medical service for women would be welcomed by all classes in this country, and the possibility of creating such a service is certainly worth careful and impartial consideration.

In this relation it may be pointed out that a council meeting of the Association of Medical Women in India was held in Ludhiana last month. A letter was sent to His Excellency the Viceroy urging the necessity for a properly organised Government service of medical women in India. A memorial was forwarded to Her Excellency Lady Hardinge petitioning for the formation of college hostels for women students in all the university cities where mixed education is carried on in India. It was pointed out that such hostels have been at work most successfully in all the large educational centres in England for very many years. Each hostel should be under the guidance and control of a lady warden, who should be experienced in educational methods, should be attached to the professional staff of the teaching institution, and when possible should herself have a university qualification. The council of the association, while admitting that there are numbers of women whose social and religious customs prevent them from making use of these centres of mixed education, is of opinion that the formation of such hostels, which would be designed for the reception of students of arts, law, science, and medicine, would very greatly help to attract women of the higher social ranks both amongst Indians and the domiciled community. A note was sent to the Director-General, Indian Medical Service, begging for the appointment of women inspectors who should inspect the work and conditions of life of all medical women, especially of the lower grades in remote districts. The council thinks

[1] See THE LANCET, Sept. 16th, 1911, p. 838.

that the appointment of such inspectors, the need for whom has so long been recognised in the educational department, would do much to improve the character of the medical work, and to alleviate the scandals which arise from time to time among the lower ranks of the female medical profession. The council welcomes the inquiries that the honorary secretary of the Countess of Dufferin's Fund is making bearing on the improvement of the class of medical women working under the fund, and considers that the standard of the preliminary examination should be raised. It strongly deprecates requiring a shorter period of training or a lower standard of examination from women than from men, and considers that no scholarships for medical training should be granted except on the results of competitive examinations. The character of successful candidates and their general fitness for the profession should, however, be carefully scrutinised before scholarships are actually awarded.

Lucknow Medical College.

The new medical college at Lucknow, the foundation stone of which was laid at the end of 1905 by His Majesty King George as Prince of Wales, and the construction of which is now complete, was opened with due ceremony by Sir John Hewett, Lieutenant-Governor of the United Provinces, on Jan. 25th. A large gathering of prominent gentlemen of the provinces and many ladies assembled on the occasion. The new college and hospital at Lucknow have been erected as a memorial of the visit of the King-Emperor and the Queen-Empress to India in 1905–06. A memorial was started for the purpose, and the total reached close on £80,000. The full cost of the project, of which only the college is so far finished, is estimated roughly at £200,000, the balance having been provided with the assistance of the Government of India and the local government.

The Prevention of Malaria.

The committee of the Bombay corporation appointed to consider Dr. C. A. Bentley's report on malaria in Bombay has presented a report. As a result of this the corporation has sanctioned the expenditure of an annual sum of nearly £5000 for a special staff.

Jan. 30th.

UNITED STATES OF AMERICA.

(FROM OUR OWN CORRESPONDENTS.)

Modifying the Milk Regulations.

THE severity of the regulations of the Department of Health regarding the quality of milk to be sold in New York has undergone some modification, as it was found impossible to enforce them without at the same time permitting an increase in the price of milk, an event that would have caused great hardship. The new regulations, adopted on Jan. 4th, are as follows:—

Section 56 *a*.—All milk held, kept, offered for sale, or sold and delivered in the city of New York shall be so held, kept, offered for sale, or sold and delivered under either or any of the following grades or designations and under no other, and in accordance with such rules and regulations as may be adopted by the Department of Health—namely:—

Grade A, for Infants and Children.—1. Certified or guaranteed milk. 2. Inspected milk (raw). 3. Selected milk (pasteurised).

Grade B, for Adults.—1. Selected milk (raw). 2. Pasteurised milk.

Grade C, for Cooking and Manufacturing Purposes only.—Raw milk conforming to the requirements for Grades A and B, not condensed skimmed milk; condensed or concentrated milk.

The provisions of this section shall not apply to buttermilk, or to milk products commonly known as kumyss, matzoon, zoolak, dried milk, or milk powder, or to other similar preparations, or to cream or modified milk.

Special permits are required for the sale of any grade of milk, the only exception being condensed milk sold in hermetically sealed tins.

Lowered Death-rate.

The Department of Health of the city of New York has made public its calculations regarding the death-rate for 1911, which is 15·13 per 1000, surpassing the excellent figure attained in 1910, when it was 15·98, the lowest in the history of the city up to that time. There were 134,542 births in the city during 1911, and 48,765 marriages; the total deaths were 75,243, over 13,000 less than the average for the whole decennium.

Gift to the New York Academy of Medicine.

Mrs. E. H. Harriman, widow of the late railway millionaire, has made arrangements to permit the Academy of Medicine, the representative professional organisation of the city, to undertake a work which in health matters will, as it were, parallel the activities of the Bureau of Municipal Research in financial matters. She has employed a trained statistician to carry out the practical details of the work of a medical committee. Among the duties of this committee are to collect facts in regard to public health, sanitation, and hygiene; to establish coöperation among all the health organisations of the city; to keep the profession advised of current health conditions; to render authoritative opinions on health matters to the public schools, health departments, and the public generally; and to make close and constant scrutiny of the hospitals and dispensaries of the city.

A Successor to Dr. Walter Wyman.

The vacancy caused by the death of Dr. Walter Wyman, Surgeon-General of the Public Health and Marine Hospital Service, has been filled by Dr. Rupert Blue, of South Carolina, who has been connected with the service for many years and is distinguished on account of his success in abolishing plague from San Francisco. In making the appointment the President has announced that it is for four years only, instead of for life as heretofore.

Increased Manufacture of Liquor.

The year 1911 has been a record year for the manufacture of alcoholic beverages, surpassing the hitherto unapproached figures for 1907. The year's production of distilled spirits amounted to 175,402,395 gallons, and that of beer and ale to 63,216,851 gallons. The amount of liquor now held to ripen in bonded warehouses is 249,279,346 gallons.

Typhoid Prophylaxis.

An example which will probably be quickly followed by all other militia regiments in the country has been set by the Seventy-first Regiment, National Guard of the State of New York, the officers and men of which were inoculated against typhoid fever last week with serum obtained from the medical department of the regular army. All officers and enlisted men of the army under the age of 45 years are now inoculated, and all recruits enlisting henceforth will be obliged to submit to the prophylactic vaccination.

Christian Science on the Isthmus.

The President has issued an order permitting Christian Scientists to practise their form of healing in the Canal Zone.

Mortality from White-lead.

A bulletin issued by the State Bureau of Labour of New York states that there were 60 deaths from poisoning with white-lead during the past year. Of the 60, 37 were painters, 8 were labourers, 4 were printers, and 2 were merchants; there was 1 each among machinists, moulders, smelters, tinsmiths, salesmen, brush-drawers, glaziers, porters, and coopers.

Blow to a National Habit.

An order has been issued forbidding the use of chewing gum in the navy. Gum was enormously popular among the "jackies," and was sold in immense quantities from the ships' stores. Captain W. F. Fulham, of the U.S.S. *Mississippi*, drew the Navy Department's attention to the interference with discipline caused by this practice, with the consequence that the gum was ordered to be no more sold or used on board ship. The popularity of gum-chewing in America has been attributed to national nervousness and other causes, the most probable of which is the great dryness of the atmosphere.

Acute Poliomyelitis.

The number of deaths from acute poliomyelitis in the United States Census Bureau's death registration area in 1910 was 1459, as compared with 569 in the previous year, the first year in which the disease was differentiated from the other diseases of the spinal cord. The death-rates per 100,000 of population for 1910 and 1909 were 2·7 and 1·1 respectively. In 1910 the largest number of deaths (310) was registered for the month of September, while in 1909 the

month of maximum mortality from acute poliomyelitis was October. The deaths of males exceeded those of females in both years, but in a somewhat larger proportion during the year 1909.

Increase in Insanity.

There are now 37,303 more cases of insanity in the United States than there were six years ago. While the total population has increased 11 per cent. in that time, the increase in insanity amounts to 25 per cent. Massachusetts, of which the chief city is Boston, leads with 344·6 insane per 100,000 population, with New York State a close second with 343·1 per 100,000.

Epidemic of Cerebro-spinal Meningitis in the South-West.

Cerebro-spinal meningitis is present in epidemic form in many districts of the South-Western States of America. The disease has been prevalent in parts of Texas for some time, and is reported to be now spreading in Oklahoma. In Springfield, Mo., there have been several cases. A detention camp has been established in Shreveport, La., for persons coming from the infected districts of Texas, while officers of the Public Health and Marine Hospital Service are coöperating in Texas with the State Department of Health in fighting the disease.

Increase of Street Accidents in New York.

According to a report issued recently by the National Highways Protective Society deaths due to vehicular traffic during January, 1912, in the streets of New York City show an increase over the same month last year. In January, 1911, 22 persons were killed in street accidents, whereas in January last 29 met their death in a similar manner. Motor-cars caused the death of 11 persons, electric street-cars caused the death of 10, while wagons killed 8. 219 people were injured during the same month.

National Control of Quarantine of the Port of New York.

At a recent meeting of the New York Academy of Medicine several speakers advocated the establishment of national quarantine for the port of New York. At the present time New York, Boston, Providence, and Baltimore are the only quarantine stations in the country that are not controlled by the Federal Government. The consensus of opinion of the meeting seemed to be that the inclusion of these ports under national control would be in the interests of public health. Prominent among the speakers who urged the adoption of the project was Dr. Leland E. Coffer, assistant surgeon-general of the United States Public Health and Marine Hospital Service.

Instruction of the Laity.

A series of 45 lectures has been arranged to be given at the New York Academy of Medicine by well-known medical men in the city to audiences of laymen. These lectures, which are being largely attended, are likely to prove of great educational value. They take up nearly all the modern problems of the profession and the newer methods of treatment by vaccines and so on, the questions of alcohol and narcotic drugs, the care of the newborn, the peril of venereal disease, and other subjects.

New Hospital Buildings.

The new buildings of the New York Post-Graduate School and Hospital greatly increase the facilities of the institution. The additions include new operating rooms and wards for both paying and non-paying patients; there is also an immense increase in the surgical armamentarium. There are 480 rooms in the new building, which has cost over £300,000. The Mount Sinai Hospital received over £89,000 during the past year, a considerable part of which will be spent on the completion of the new pathological laboratory now in process of erection. A hospital for sick animals will soon be realised, over £16,000 having been raised by the New York Women's League for Animals in the last two months, £5000 of this amount coming from one enthusiast.

Official Exoneration of Dr. Wiley.

The house committee on expenditures in the Agricultural Department in its recent report to Congress completely exonerated Dr. Harvey W. Wiley as far as the accusations brought against him for malfeasance in office were concerned.

Proposed Action in Regard to Fee Splitting.

In a report to the Board of Regents of the State of New York the State Commissioner of Education has recommended that drastic action be taken, even to the revocation of licences of those found guilty, to prevent the splitting of fees between the general practitioner and the surgeon or consulting physician. The Commissioner cites the report of the Erie County Medical Society on the subject of fee-splitting, which that society reported to exist among its members to a deplorable extent, and suggests to the legislature that it consider the advisability of amending the law to prohibit a consulting physician or surgeon from paying fees to another practitioner for bringing him "business" without making the fact of such payment known to the patient.

Feb. 8th.

Obituary.

SIR WILLIAM HENRY ALLCHIN, M.D. LOND., F.R.C.P. LOND., F.R.S. EDIN.,

PHYSICIAN EXTRAORDINARY TO THE KING; CONSULTING PHYSICIAN TO WESTMINSTER HOSPITAL.

By the death of Sir William Allchin, which took place on Feb. 8th after a long illness, the medical profession has lost a sagacious and indefatigable leader who by his personal labour and his influence added much to the general progress of medicine. In the administration of the Royal College of Physicians of London he had been a source of strength for many years, while as an authority on the intricate subject of the constitution of the University of London he had no rival.

Born in Paris on Oct. 16th, 1846, Sir William Allchin was the eldest son of the late Dr. Allchin, of Bayswater, and was descended from old Kentish stock. After being educated privately he entered as a medical student at University College, London, where his progress was marked by the same thoroughness which characterised his later life. In 1869 he qualified by taking the Membership of the Royal College of Surgeons of England and the Licentiateship of the Society of Apothecaries of London, and two years later he graduated as Bachelor of Medicine at the University of London, gaining the Scholarship in Medicine and the gold medal. In 1878 he became a Fellow of the Royal College of Physicians of London. His early medical career was associated with University College and its attached hospital, and he was at one time lecturer on comparative anatomy and animal physiology at University College, but it was at Westminster Hospital that he obtained the experience upon which the work of his life was based. Here as assistant physician and afterwards physician, joint lecturer on the principles and practice of medicine, dean of the medical school, and emeritus lecturer on clinical medicine, he became known among his contemporaries and his pupils alike as a singularly able teacher with a gift of organisation and a passion for work. These qualities led to his election to the Senate of the University of London, and to his appointments upon the Consultative Board of the Medical Service of the Royal Navy, as well as of the Army and Indian Medical Services. He was also appointed examiner in medical subjects in the Universities of London, Durham, and Glasgow, and at the London Conjoint Board at different times—a record of popularity among examining boards which would be very hard to beat.

His literary and oratorical powers kept pace with his practical experience, and he delivered many public addresses of genuine merit. The official lectures which he gave from time to time in connexion with the Royal College of Physicians of London and different learned societies, connected or not with the medical profession, were always marked by thoroughness, conciseness of statement, clearness, and judgment, four things which made his lectures and addresses valuable supplement to our knowledge of medicine or sociology. In the Bradshaw Lecture on Duodenal Indigestion, which he delivered in 1891 before the Royal College of Physicians of London, he mapped out the outlines and broad features and laid down a course for further study of an obscure and important subject in accordance with the then physiological knowledge and the prevailing conceptions of pathology. In 1896 he delivered the annual oration before the Medical Society of London, of which he was one-time president and for 18 years an admirable librarian. This address, entitled "The Breaking Strain," dealt with the subject of death and its cause. "A review of all

the circumstances would seem to show," he said, "that failing vitality follows the cessation of reproductive capability rather than that this latter fails because of approaching death, and, if we may speculate with others, it appears to be among the possibilities that the lacking stimulus is to be found in connexion with the sexual elements themselves—some ferment, may be, such as we assume to exist in these lately recognised internal secretions, the potency and influence of which in respect to nutritive processes we are but just gaining a glimpse of." Suggestive ideas and bold conceptions of this sort were common in his conversation and public utterances.

In 1897 he delivered the address at the Hunterian Society on Some Relationships of Indigestion, setting forth some considerations which he thought were essential preliminaries to the formation of a diagnosis and a rational treatment of indigestion. The Study of Structure in Relation to Function was the subject of the Harveian Oration which he delivered in 1903, and the following remarks with which he concluded the oration are important as showing again the wide range of his conceptions.

> While I have endeavoured to illustrate with such completeness as my brief time permits the relationships of physiology to anatomy, whether normal or morbid, the general tenour of my remarks will have indicated that when the limits of visibility, even with our most perfect instruments, have been reached the separate investigation of structure and of function no longer becomes possible. The molecular constitution, chemical or electrical, of living matter becomes conceivable only in terms of action, and function and structure are but aspects of each other. No deeper secrets of nature exist to be searched out by observation and experiment than these, and none will more benefit mankind in their discovery.

In the Lumleian lectures which he delivered in 1905 on Nutrition and Malnutrition there is an elaboration of his earlier thoughts on the subject of the cessation of vitality. In these lectures he summarised some of the problems in the biochemistry of nutrition, and succinctly declared that as it appeared to be possible by the application of certain electrolytes to avert from a living ovum what may be termed its natural death, the degeneration and death of the tissue cells of higher organisms might be averted; at any rate, a search in this direction should no longer be looked upon as a hopeless quest."

"A Manual of Medicine," in five volumes, edited by Allchin, appeared, the first volume in 1900 and the last in 1904. He himself contributed articles to these volumes, which were all stamped by a high level of excellence. Among his other contributions to the literature of medicine, in addition to the last-named manual, were articles on Disorders of Digestion and Diseases of the Intestines in "Quain's Dictionary of Medicine," on Diseases of the Stomach in "The Encyclopædia Medica," and Diseases of the Peritoneum in "Allbutt's System of Medicine." Besides these he contributed many articles to THE LANCET, the West London Hospital Reports, and "Keating's Cyclopædia of Diseases of Children." In 1908 he published "Methodus Medendi."

Sir William Allchin married Margaret, eldest daughter of Alexander Holland, of New York, in 1880, and was created a Knight in 1907. In March, 1909, his friends and old pupils presented him in the board room of Westminster Hospital with his portrait as a mark of their high regard.

Dr. de Havilland Hall, for many years Sir William Allchin's colleague on the staff of the Westminster Hospital, bears intimate testimony to qualities which we have only indicated above in a summary of Sir William Allchin's work. He writes:—

"Allchin was a born organiser, and had such powers of administration that he would have made an excellent Secretary of State. At the Coronation of King George V., all the medical arrangements in Westminster Abbey were under his supervision, while he also undertook the distribution of seats in the vast stand erected by the Westminster Hospital. Both these tasks were carried out with his usual tact and thoroughness, and to the entire satisfaction of all concerned. The outstanding feature in his character illustrated in such undertakings as these, was his unswerving adherence to what he considered his line of duty. This was particularly shown on the occasion of his resigning the post of assistant registrar of the Royal College of Physicians of London, at the time when the majority of the Fellows decided upon a plan of action in regard to the University of London which he considered unwise. He took this step so that, being relieved of responsibility, he might regain the freedom to pursue such course as might seem desirable to him in the circumstances, and in doing so he earned the commendation of many Fellows.

"He was an admirable teacher, and his teaching was much appreciated by the students of the Westminster Hospital He impressed upon them by precept and example the necessity for a thorough investigation of every patient coming into the wards. Though he never laid himself out to coach men for examination purposes, his large experience as an examiner naturally influenced his teaching. He was fair as well as loyal, and one of the first before whom all difficulties, whether of scientific or administrative sort, were laid by his colleagues.

"Allchin did not make friends easily, as he had a certain degree of reserve in his manner, and he was very reticent in expressing his deeper feelings, but those who had the privilege of his friendship could rely upon him, and even acquaintances realised that he was a man to be respected and trusted, But reserved as he certainly was, he was the most admirable and generous of hosts. There was nothing he enjoyed more in recent years than walking about the lanes of his ancestral county of Kent and inspecting all the interesting churches or buildings that he encountered. It was a source of great pleasure to him when he was able, some years ago, to acquire a delightful old black and white house at Plaxtol. This he restored with taste and judgment, and he seemed to have no greater pleasure than welcoming his friends there. He was a charming host, full of conversation, and he had the power of adapting himself to the capacity of his listener. Not only in the country did he exercise his hospitality. In London he gave dinners on a large scale at his clubs—the Athenæum and Conservative—where he entertained the leading men in medicine, science, and the arts. He was much impressed with the useful effect of men of different views meeting at dinner and airing their ideas, and one of the best things he ever didfor the Westminster Hospital Medical School was instituting the school and staff dinner. The members of the staff of the school and hospital dine together three times a year, and this opportunity of friendly intercourse has had a powerful influence in securing the harmonious coöperation of the staff in the work of the school and hospital. Allchin was the first secretary to the club, which has now been carried on for 40 years.

"The affectionate regard in which he was held was testified by the large number of friends who assembled at East Malling on Thursday, Feb. 15th, to see him laid to rest by the side of his grandfather, also William Henry Allchin."

An old friend and pupil writes:—"To all old Westminster men the death of Sir William Allchin will come as a grievous shock, for no man ever worked harder for his hospital than did the late Sir William. Courteous and dignified, he was indeed the type of what a consultant physician should be. No one ever heard him utter a derogatory word of a brother practitioner, and I am equally sure that no brother practitioner ever spoke slightingly of him. It is, however, of his unique powers as a clinician that I would speak. His early morning cliniques on a Friday were truly *sui generis*. Sir William would not take his class perfunctorily round his beds, but would select one or two cases to demonstrate for the two or three hours that he was in the hospital. These cases would be gone into most minutely, so that no one could leave the clinic without having learnt something of importance for his own practice. By question and answer, and by illustration from the rich store of his own personal experience, the students would have instilled into them all the essential features of the case. He was the possessor of the gift of a quaint genial raillery which never wounded the feelings of anyone at whom it was directed. Westminster men must of a surety have been well grounded in the science and art of medicine by their old teacher, for Allchin was completely familiar with up-to-date pathology of disease in all its aspects, at the same time that he was a master of the practice of his profession. May the earth lie lightly upon him, now that his labours are finished."

GERHARD HENRIK AMAÜR HANSEN.

THE death is announced of Dr. Gerhard Henrik Amaür Hansen, whose name is associated with the discovery of the bacillus of leprosy. Dr. Hansen was born on July 29th, 1841, and he early made his name as an authority on leprosy in its clinical aspects. In 1873 several years of laborious investigations were rewarded by his discovery of the bacillus of leprosy,

the recognition of which formed the basis of rational treatment of this disease for the first time. But though Hansen's bacteriological work brought him international fame and honours, his clinical and legislative work were even more appreciated in Norway, where his vigorous and untiring efforts to stamp out the disease were rewarded with striking success. Leprosy, which had been a national scourge on the west coast, became in the course of a few decades a rare and unfamiliar complaint. At the close of the nineteenth century the hospital accommodation for leprosy so far exceeded the needs of the nation that one of the large hospitals near Molde was converted into a sanatorium for consumptives, and within the last four years a further reduction of hospital accommodation for lepers has been contemplated. In 1909 Hansen's system for the control of leprosy was unanimously admitted to be the most satisfactory in practice by the members of the Second International Leprosy Congress in Bergen, and he was elected as Virchow's successor to the vice-presidentship of the International Leprosy Committee. Although his work on leprosy occupied much of his time, his interests were numerous, and he was particularly devoted to the study of evolution and Darwin's theories, of many of which he was a keen supporter. His publications on leprosy alone are very numerous and in many languages. His advanced years were no hindrance to a life active till the last, and he was travelling on the west coast of Norway at the time of his death. He had retired on the evening of Feb. 11th, and on the following morning he was found dead in his bed. His many friends, both at home and abroad, will learn with sorrow of his death, which robs Norway of her most distinguished scientist of the present day.

RICHARD LINGARD STOKES, M.R.C.S. ENG., L.R.C.P. LOND.

THE death is announced at Ditchling, nestling at the foot of the Southdowns in Sussex, of Mr. Richard Lingard Stokes, and the mere fact that he had practised there for over 30 years is evidence enough to show that he will be greatly missed. Son of Mr. Lingard Stokes, of the Indian Civil Service, he was born in Worcestershire 58 years ago, and was educated at Cheltenham and Oakham Schools. Passing on to the University College, London, he became M.R.C.S. in 1877 and L.R.C.P. in 1878. He was married at Maidenhead a year later and settled at Ditchling. He held a number of public appointments, and took quite an active interest in the affairs of the village and the immediate district. In his younger days he was a keen cricketer. He, too, was very fond of music, and in this connexion was always to the fore with his wife in local musical gatherings. His health had given cause for anxiety for some time.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced: Dr. Julius Pagel, extraordinary professor of the history of medicine in the University of Berlin, aged 60. In early professional life he held Poor-law and school appointments in Berlin. During this time he applied himself to the study of the historical aspect of medicine, and was fortunate enough to bring to light many mediæval manuscripts which had been until then unknown. After becoming a recognised lecturer on the history of medicine in the University he published numerous works and papers on the history and the ethics of medicine, and contributed to Neuburger's "Text-book of Medical History." He was also librarian of the Berlin Medical Society, and one of the editors of the international review of the history and geography of medicine, *Janus*. He was granted the title of professor in 1898, and in 1902 was appointed extraordinary professor.—Dr. Hermann Jastrowitz, an eminent Berlin alienist, at the age of 72. He was for many years assistant in the mental clinic of the Charité under Westphal. In collaboration with Leyden he published a well-known work on the anatomy of the brain. As a medical orator he was in great request at professional gatherings, and was secretary to the Society of Medicine and Pædiatry.—Dr. L. Benech, formerly inspecting medical officer of the French Military Medical Service.—Dr. E. Caventou, formerly President of the Paris Academy of Medicine.—Dr. von P. Ivanovski, formerly professor of pathological anatomy in the St. Petersburg Military Medical Academy.

THE NATIONAL INSURANCE ACT.

COMMITTEE ON TUBERCULOSIS.

THE Chancellor of the Exchequer is appointing a Committee to report at an early date upon the consideration of general policy in respect of the problem of tuberculosis in the United Kingdom, in its preventive, curative, and other aspects, which should guide the Government and local bodies in making or aiding provision for the treatment of tuberculosis in sanatoriums or other institutions or otherwise.

The Committee will consist of:—

Mr. Waldorf Astor, M.P. (Chairman).

Dr. Christopher Addison, M.P.

Dr. N. D. Bardswell, Medical Superintendent of the King Edward VII. Sanatorium, Midhurst.

Mr. David Davies, M.P., President of the King Edward VII. Welsh National Memorial Association.

Dr. A. Mearns Fraser, M.D., Medical Officer of Health, Portsmouth.

Dr. A. Latham, Physician at Mount Vernon Hospital for Consumption.

Dr. W. Leslie Mackenzie, Medical Member of the Local Government Board for Scotland.

Dr. J. C. McVail, Medical Member of the National Health Insurance Commission (Scotland).

Dr. W. J. Maguire, Medical Member of the National Health Insurance Commission (Ireland).

Sir George Newman, Chief Medical Officer of the Board of Education.

Dr. Arthur Newsholme, C.B., Medical Officer of the Local Government Board.

Dr. James Niven, Medical Officer of Health of Manchester.

Dr. Marcus Paterson, Medical Superintendent of the Bromptom Hospital Sanatorium, Frimley.

Dr. R. W. Philip, Physician of the Royal Victoria Consumption Hospital, Edinburgh.

Dr. H. Meredith Richards, Medical Member of the National Health Insurance Commission (Wales).

Mr. T. J. Stafford, C.B., Medical Member of the Local Government Board for Ireland.

Miss Jane Walker, M.D., Medical Superintendent of the East Anglian Sanatorium, Nayland, Colchester.

Mr. J. Smith Whitaker, Medical Member of the National Health Insurance Commission (England).

The Secretary to the Committee will be Mr. F. J. Willis, one of the assistant secretaries of the Local Government Board.

INCORPORATED SOCIETY OF HOSPITAL OFFICERS AND THE NATIONAL INSURANCE ACT.

A largely attended meeting of this society was held on Feb. 16th in the great hall of St. Bartholomew's Hospital, under the chairmanship of Mr. KERSHAW, to hear an address from Mr. Worthington Evans, M.P., on National Insurance and the Voluntary Hospitals, and to discuss the new Act.

The CHAIRMAN pointed out that one of the functions of the association was to discuss questions of interest to hospital workers with the view of coördinating those interests and securing unanimity of thought and action on questions of hospital policy.

Mr. WORTHINGTON EVANS then delivered an address on the new Act, with special reference to its effect upon hospital workers. The sections specially concerned were 12 and 21. In the first of these sections he defined the sources of income, the first of which depended upon an agreement having been made between the hospital and the society of the insured person, and also depended upon that person having no one dependent upon him. The second was a voluntary payment which might be made in the case of a doubly insured woman, of which latter there would not be many relatively. Under Section 21 there was a possible source of income—namely, that the Friendly Societies and the County Committees might (there was no compulsion) subscribe to the hospitals. The amount which those bodies might subscribe under Section 21 was two-ninths. He pointed out that the Act did not include any hospital benefit; there was a sickness benefit, a disablement benefit, a maternity benefit, a sanatorium benefit, the latter being limited to treatment in sanatoriums for tuberculosis and similar diseases, and such others as might hereafter be

specified. One very important fact stood out—namely, that for every male or female employee of a hospital, the hospital as such would have to make a weekly contribution. In a hospital with 250 beds there would be probably 32 males employed, and 128 females, or a total of 160, and the annual tax payable by the hospital for them would be £104. It seemed odd that these people, surrounded by all the appurtenances for good health, should be expected to be included when they had hitherto received any necessary medical treatment for nothing. He expressed the opinion that the attendance in the out-patient departments of hospitals would be less than hitherto. Some of those who had been in the habit of attending hospital would now be treated privately, and to the class of deposit contributors it would probably make no difference, as these would frequently be out of benefit. But he believed there would be a more numerous demand from in-patients than before. His reasons for saying that were two: It would be discovered that a large number of cases required and deserved treatment in a hospital for conditions which would not have been known of before, and which might have gone on to death without proper skilled attention. Secondly, if a doctor was compelled by contract to take in greater quantities of patients, that doctor would discover which patient was a troublesome person, and he would feel the temptation which the German doctors had fallen into of transferring such patients to a hospital. He did not believe there would be any great reduction in subscriptions to hospitals, but thought that the Act would quicken the public conscience as to the necessities of the less fortunate members of the community. In conclusion, he dealt in detail with the question of finance, and gave the proportions of contributions from working people in two provincial hospitals, the Royal Victoria Hospital at Newcastle-on-Tyne, and the Essex County Hospital at Colchester. In the first of these the income from all sources was £33,000, and the workmen's contributions amounted to £17,000. At the Colchester Hospital out of a total of £954 the workmen contributed £345. He also dealt with the Clapham Maternity Hospital as an example of a charity, one which was recognised as such in so far that the Income-tax Commissioners returned the tax to the institution. He advised that kind of hospital to make arrangements quickly with an approved society which would administer the benefits. With regard to men employed in hospitals, most men were in a society of some sort, so that before hospitals attempted to form a separate society for men they should ascertain whether there was any real demand for such on the part of their male staff. But with regard to the women, there was a special reason for the nurses having a society of their own, especially one with 5000 members or over, for then should there be any surplusage they would be entitled to one-third of it.

After various members had asked questions, Dr. F. J. POYNTON, speaking as a medical man on the staff of a hospital, remarked that a number of medical men on those staffs had signed a pledge not to work under the Act. If the medical profession refused to go on panels he wished to know what the position of medical men connected with large voluntary hospitals would be. As a voluntary worker in a voluntary institution he took it that one would not be technically working under the Act. He asked if some contributions were made to the hospital from insured people, as voluntary workers in that hospital would such doctors be considered as working under the Act? Of course patients were there and must be attended to, but a reply to his question would be very helpful. To this Mr. EVANS replied that the fact of being a voluntary worker almost defined the position. A contribution to a hospital by a Friendly Society was a mere grant; it conferred no rights whatever, and in the absence of any right there was no contract. Consequently a medical man would not put himself in opposition to his pledge by working for a hospital which had obtained such a contribution.

Mr. W. MCADAM ECCLES drew a comparison between the economically-worked State hospital in Germany and the voluntary hospitals of England. In a German State hospital of the same size as St. Bartholomew's, with 600 beds, there were 50 nurses, whereas St. Bartholomew's had 344.

Sir JOHN YOUNG dwelt upon the blessing of English voluntary hospitals and the degree of efficiency and skill attained, and expressed, in vigorous terms, his opinion of the Act and the undue haste with which he contended it had been passed into law.

BRITISH MEDICAL ASSOCIATION: SPECIAL REPRESENTATIVE MEETING.

The fourth meeting of the Representative Body since the introduction of the National Insurance scheme was held in the Court of Common Council Chamber of the Guildhall, London, on Tuesday and Wednesday, Feb. 20th and 21st. For permission to publish the following report from a member of our staff who was present we are indebted to the executive of the Association, who extended the same courtesy to THE LANCET at the previous Representative meetings.

The proceedings opened at 10 A.M. on Tuesday. An extremely heavy and complicated programme was before the Representative Body. Over 370 separate motions, amendments, and riders, mainly arising out of the report of the Council, were upon the agenda paper.

Immediately after the formal business had been concluded, the Chairman of the Representative Body rose to ask for an expression of feeling from the meeting as to his personal position. In order to settle this point at once he desired that a rider standing in the name of the Bradford Division, and numbered 359 on the agenda, should be taken before any other business. Otherwise, with that vote of censure hanging over him, he felt himself unequal to the conduct of the meeting. The rider was: "That Dr. Maclean be asked to resign the chair and a more vigorous advocate of our rights be elected." After considerable discussion it was decided to take this matter first, in accordance with Dr. Maclean's wish. Dr. J. A. Macdonald then took the chair for the time being. Each speaker who supported the vote of censure expressed his personal regret at being compelled to do so, and confined his criticisms to public grounds. No personal allegations whatsoever against Dr. Maclean were entertained. After a close discussion a card vote was demanded and agreed to.

Dr. MACLEAN, speaking in his own defence before the motion was put to the vote, said it had rarely been vouchsafed to any man to have such an opportunity as he had had that day of seeing himself as others saw him. Those members who thought well of him had stated his qualities in a positive sense too highly. On the other hand, he thought those who had taken the contrary view had put his shortcomings rather too strongly. In fact, he had never before realised so strongly the possibilities of one individual possessing the qualities of both Dr. Jekyll and Mr. Hyde. He had no sort of complaint to make as to the tone and content of the debate; it had been worthy of the highest traditions of the Representative meetings, but it also showed that he was right in asking that the matter should be dealt with at the opening of the proceedings. The main points in the indictment against him were first, *suppressio veri* in regard to the speech he made in reference to certain rumours; and second, an alleged misdirection of the Representative meeting. On the first point it was suggested that he wilfully misled the Representative meeting in that he gave the meeting to understand that no question had arisen regarding the possible receipt of an offer to any member of the Association to act as one of the Commissioners. The rumours which were in his mind when he spoke were to the effect that for prospective personal gain of various kinds the officials of the Association had immorally used their official position to give away points in the policy of the Association. No words of his were too strong to repudiate such a charge. Furthermore, he said that every man with whom he had the honour of being associated in the work was absolutely to be trusted in that and every other sense, and he saw no reason whatever to depart from the association of that sentence with what had gone before. As to the suppression of details of the interview with the Chancellor, Mr. Lloyd George inquired as to the Medical Secretary's abilities, and he (Dr. Maclean) gave his opinion. He made a communication to the Medical Secretary after that interview, and, rightly or wrongly, he regarded the conversation with Mr. Lloyd George, with its negative result, as confidential. The question had been put: If that were so, why did he feel called upon to refer to the fact at the Representative meeting? The reason was that the considerations governing the position were that an offer had then been definitely made by the Prime Minister to the Medical Secretary. The question being in a positive phase, when the Medical Secretary placed himself in the hands of the Council he (Dr. Maclean) thought it best to inform the Council of the whole of the

circumstances. As to the alleged misdirection of the Representative meeting, he admitted that, looked at in cold print, his answer to the question as to the duty of Representatives in the circumstances that had arisen was unwise and inaccurate. He confessed he had not the words of By-law 39 (3) in his mind at the time. The Representatives were faced with new facts and they asked what was to be their relation to them. In speaking as he did, he had in mind the margin of discretion left to Representatives in their actions. He left himself entirely in the hands of the meeting in these matters, but to import into either of the two indictments a deliberate attempt on his part to mislead the Representatives or to deceive anybody was very unjust. He knew his shortcomings, but he could say, with an absolutely free conscience, that to the best of his ability he had served the profession faithfully and well. Dr. Maclean added that whatever might be the result of the vote it was absolutely unfounded to suppose that he would be turned from a friend into an enemy; whatever action the meeting took he would deflect never by one iota from the dominant principle that had been in his mind, that he would stand by the cause of the profession and would devote himself in every possible way within the limit of his time and ability to serving the cause of the men whose interests he had at heart.

After an adjournment for the counting of votes the result was announced as follows: For the rider, 63 constituencies, representing 6327 members; against, 78 constituencies, representing 7597 members. The vote of censure was therefore lost. Eight Representatives present did not vote. At 12.30 P.M. Dr. Maclean resumed the chair amidst applause, and asked all present to forget what had just happened and to stand shoulder to shoulder in the face of the present critical situation. Votes of condolence and regret with the families of Lord Lister and Sir Henry Butlin were carried in silence, all standing up. A special Agenda Committee was then appointed to evolve order out of the immense mass of business before the meeting, and a two hours' adjournment was made for this purpose and for luncheon.

On the resumption, business connected with standing orders was disposed of, and the Council's and other reports were formally received. The Representative Body then went into committee under the able chairmanship of Mr. T. Jenner Verrall. The order of business recommended by the Agenda Committee was agreed to. In view of the vast number of items each could not be discussed seriatim. It was decided that the first subject to be settled should be that of Recommendation VI. in the Council's report—viz., the future State Sickness Insurance Committee, its functions, powers, and constitution.

After keen and prolonged discussion the recommendation of the Council was passed in the following amended form:—

That a State Sickness Insurance Committee be appointed to consider and report to the Council on all matters connected with the National Insurance Act or a Public Medical Service. That the State Sickness Insurance Committee consist of (*a*) 24 members (the majority of whom shall be general practitioners), elected by the Representative Body, (*b*) the *ex-officio* members, (*c*) two women medical practitioners to be co-opted by the Committee, one of whom shall be nominated by the Northern Association of Medical Women, the other by the Association of Registered Medical Women; and that the Committee be empowered to add to its numbers for special purposes not more than four additional members.

An amendment, designed to place all executive power in connexion with the Act in the hands of the new Committee, was proposed by Dr. T. A. HELME, but was eventually negatived. The method of choosing the 24 members to be elected by the Representative Body was considered until after the dinner interval. The meeting then considered Recommendation I. of the Council's report.

Recommendation I. of the Council's report was next taken. An amendment, "That the Council be instructed to at once cease negotiations with the Government and the Commissioners," was debated and negatived by a very large majority. A further amendment, "That the Council be instructed to inform the Government and the Insurance Commissioners that until the minimum demands of the profession are placed beyond doubt in an amending Act of Parliament, further negotiations will be useless," also raised a plain issue, and both sides were vigorously represented. The vote was taken by roll-call, and the result was that the amendment was lost by 81 votes to 58. This closed the first day's proceedings, and the meeting adjourned at 11.15 P.M.

On Wednesday morning, after the minutes of the previous day had been passed, consideration of amendments arising out of Recommendation I. was resumed, and nominations for the election of members of the new State Sickness Insurance Committee were received. An important amendment standing in the name of the Winchester and other Divisions was closely debated. It was indicated that if the original amendment were modified a basis of unanimity might be reached. To this end the proposer agreed to the following revised form of his motion:—

That this Representative meeting direct the Council to inform in plain and unmistakable language the Commissioners appointed under the Insurance Act, 1911, that unless the minimum demands of the Association be embodied in the Regulations to be issued by the Commissioners in such a manner as shall be effectual and permanent, with a view to having the same embodied in an amending Act, it is the intention of the British Medical Association to call upon its members and upon all other medical practitioners to decline to form panels or undertake any other medical duties which may be assigned to them under the Act, in conformity with the undertaking which has already been signed by over 26,000 medical practitioners.

The vote was again taken by roll-call and the amendment was declared carried, amidst great applause, by 159 votes to 3, and as a substantive motion it was carried unanimously. Thus Recommendation I. of the Council's report was replaced by the revised amendment.

There was a very strong feeling that an insistence upon the retention of all disciplinary powers in the hands of the profession itself should become one of the foremost demands of the profession. After various forms of words had been considered, it was resolved that the power of removing a practitioner's name from the panel and the power of dealing with all complaints against medical men on the panel should be vested in the Local Medical Committee, with right of appeal to a Central Medical Board, to be appointed for the purpose. This motion was adopted unanimously as a rider to the previous resolution.

The question of dispensing was then discussed and a rider to the following effect was carried:—

That dispensing as hitherto should be done or arranged for by the medical practitioner for his own patients, should he so desire, and paid for at the scale of tariff rate agreed upon for pharmacists by the Pharmaceutical Society.

The question of scale and method of payment for medical benefits then arose. The Chairman of Council warned the meeting that in submitting terms of remuneration to the Commissioners the profession should not merely state the sums which it thought just, but should give its reasons for insisting upon them.

Dr. J. PEARCE, chairman of Remuneration Sub-committee, then spoke by invitation, and the discussion was maintained for some time. It was felt widely that this matter should be decided by the constituencies themselves.

It was resolved:—

That the policy of the Association be to claim 8*s*. 6*d*. as a minimum capitation fee, not including extras and medicine, for members of approved societies and to claim the recognition of payment per attendance, in which case the fees must be on such a basis as shall be deemed an equivalent by the State Sickness Insurance Committee, with recognition of a £2 maximum income-limit.

The fifth recommendation, intended to leave the Council to deal with questions of underselling, was next taken and finally passed in an amended form. Then followed a debate upon the desirability of or of not taking part in Advisory Committees to assist the Commissioners in framing regulations. Here was revealed a sharp division of opinion. The discussion centred around a proposed rider:—

That the Council be instructed to take all possible steps to ensure that no members of the profession shall hold office or take any part in any advisory, administrative, or medical work under the Act until such time as the minimum demands of the profession are unreservedly conceded in such a manner that they cannot be altered or withdrawn save by Act of Parliament.

This was voted upon by roll call and was lost by 70 to 44.

The rejection led to the passing of a rider to ensure suitable representation upon the Advisory Committees; and another to secure their resignation if the profession's demands were not conceded, was also passed.

Recommendations IV., II., and III. were then carried practically as they stood before the adjournment.

It was found impossible to complete the business by Wednesday night, and an adjournment was made at 11 o'clock until Thursday morning.

The meeting was still in progress at the time of our going to press.

Medical News.

METROPOLITAN POLICE SURGEONS' ASSOCIATION.—The annual meeting of this association was held at Frascati's Restaurant on Feb. 16th. During the year 1911 two very instructive gatherings were organised, the first being held at the British Medical Association offices on May 4th, when Dr. Frederick J. Smith, lecturer on forensic medicine at the London Hospital Medical School, gave a demonstration on Poisons, their Detection and Post-mortem Appearances. The second, by the kind permission of the Metropolitan Asylums Board, was held in their board room on Nov. 8th, when a demonstration on Blood Staining and Examinations, Sera Reactions, and other Tests of Medico-Legal Importance was given by Dr. J. Milner-Adams. Mr. V. A. Jaynes was elected president for the coming year, Mr. Peter Cooper vice-president, and Mr. H. Bott treasurer. The honorary secretaries (Dr. C. Owen Fowler and Dr. G. Nicol Henry) were unanimously re-elected, and the four vacancies on the council were filled by the election of Mr. T. L. Archer, Dr. H. J. Ilott, Dr. W. Bower, and Mr. C. J. Stocker. During the year death removed Dr. C. Pinel Gallie, the honorary treasurer, in whom a genial friend and a valued officer of the association was lost. The meeting was followed by the annual dinner, which was under the chairmanship of the President, Dr. A. Dumville Roe, who was supported by Sir Frederick Wodehouse, K.C.V.O., C.B., the Assistant Commissioner of the Metropolitan Police; Mr. Clinton T. Dent, the chief surgeon; Mr. H. R. Oswald, the coroner for South-East London; Mr. Hedderwick, and Dr. F. J. Smith. After the usual toasts had been honoured Mr. Oswald proposed "The Metropolitan Police Surgeons' Association." He remarked on the great help that he as a coroner received in his court from divisional surgeons, and complimented the association on the work it was doing, especially in holding meetings for the consideration of professional matters, such as the detection of poisons and the sera reactions of blood, which would be of great help to them when giving evidence. He commented on the preventive treatment of tubercular disease, and on the great advantage that beds were now available at the Frimley Sanatorium for the reception of early cases of phthisis that might occur in members of the force. Mr. Jaynes responded. Dr. Owen Fowler gave the toast of "The Commissioners and the Receiver," which was replied to by Sir Frederick Wodehouse, who made mention of the newly to be enrolled civilian force of special constables. Mr. Bott proposed "The Chief Surgeon, Mr. Dent," and pointed out what a friend not only divisional surgeons but also police officers had in him. He facetiously remarked on the need of adequate remuneration for the profession, so that they might in future be able to pay modern taxes and have sufficient to attend the annual dinner. Mr. Dent made an entertaining reply. The dinner concluded with the toasts of the health of the guests, to which Mr. Hedderwick suitably replied, and that of "The President," proposed by Dr. F. G. Crookshank. An enjoyable concert programme was provided by Miss Edith Kirkwood, Mr. Charles C. Rose, and Miss Beatrice Eveline, the 'cello solos of the latter receiving a well-merited encore.

LITERARY INTELLIGENCE.—Messrs. W. B. Saunders Company have arranged to publish in serial form the Surgical Clinics of Dr. John B. Murphy at the Mercy Hospital, Chicago. The Clinics will be published bi-monthly. The subscription price will be 35*s.* net per year of six issues, each number containing about 130 octavo pages, illustrated. The first number appears this month.—Messrs. Constable and Co. will commence the publication in April next of a new review, to be entitled "Bedrock," "a quarterly review of scientific thought." The review will appear as an organ devoted to the full discussion of such subjects as the effect on the race of native and foreign disease, of intemperance, of city life and luxury; the fitness of women for government; the real nature of the psychological and physiological difference between sexes, races, and classes; the present relation of science to religion; theories of evolution and heredity; the trend of scientific and mechanical research, invention, and development; in fact, with all the greater problems of modern science in a manner fundamentally scientific, and, the editors hope, also generally interesting to an educated public. It will further make a feature of notes on current research work and reviews of selected scientific books. The editorial committee consists of Sir Bryan Donkin, Professor E. B. Poulton, Hope professor of zoology in the University of Oxford, Professor H. H. Turner, Savilian professor of astronomy in the University of Oxford, and Dr. G. Archdall Reid. The acting editor will be Mr. H. B. Grylls.—Mr. Heinemann will publish shortly "Microbes and Toxins in Nature," by Dr. Burnet, of the Pasteur Institute, with a preface by Professor E. Metchnikoff, author of "The Nature of Man"; "Animal Life in Africa," by Major J. Stevenson Hamilton, F.R.G.S., C.M.Z.S., descriptive of the fauna of the Ethiopian region; a book by Earl Russell on "Divorce"; and an English edition of the novels of Dostoevsky, translated by Mrs. Garnett.—The Cambridge University Press announce the issue of the new "Encyclopædia Britannica" in fortnightly parts at 3*s.* 6*d.* each. Each part will consist of about 200 quarto pages, and will be bound in stout boards.

INQUEST ON A MEDICAL MAN.—On Feb. 16th an inquest was held at Wandsworth town-hall by Mr. John Troutbeck with reference to the death of Dr. Horace Jeaffreson, aged 75, who died under tragic circumstances at his house at Wandsworth on Feb. 14th. Mr. H. C. Jeaffreson, a nephew, said that the deceased retired from practice some years ago. He had not been in good health lately, though when witness last saw him about a fortnight before his death he seemed better than usual. He was not so sane as he was 20 years ago, but he was able to talk rationally on ordinary subjects. Mrs. Charlotte Simpson, housekeeper to the deceased, whom she had known 35 years, said he suffered from delusions and nightmare, and fancied he saw faces and that he was poor. The night attendant said that on her return after a temporary absence early on the morning of the 14th she noticed a change in the face of the deceased. Turning back the bedclothes to feel if the heart was beating she saw a penknife sticking in a wound in his right groin. Dr. F. H. Carter said that he went into partnership with Dr. Jeaffreson 27 years ago. Dr. Jeaffreson retired in 1903. Lately he had been mentally depressed, though on some points his mind was alert. He suffered from hydrocele on both sides, and had been in the habit of tapping it himself on the right side when necessary. Witness used to operate on the left side. Some time ago witness and another medical man prescribed small doses of morphia. Deceased used to inject the drug himself. He was most careful and never exceeded four minims. Dr. Jeaffreson had also co-operated courageously with his advisers in reducing the dose, though morphia added enormously to his comfort. For some weeks before his death he had not used the drug. He had no suicidal tendency; on the contrary, he had a great horror of suicide. If he had intended to end his life by piercing the femoral artery he went very wide of the mark for one who knew his anatomy well. The artery was cut, but not deliberately witness thought. Dr. R. S. Trevor, who conducted the necropsy, explained that the wound was of very slight depth. It was an inch and a half in length, and its centre was an inch away from the femoral artery, which the point of the knife had reached under the skin. Death was due to heart failure. The jury returned a verdict of death from misadventure, and expressed the opinion that Dr. Jeaffreson had no intention of cutting the artery.

SEVENTEENTH INTERNATIONAL CONGRESS OF MEDICINE.—A meeting of the organisation committee of the Congress was held on Monday, Feb. 19th, at 5 P.M., in the library of the Royal College of Physicians of London. Sir Thomas Barlow presided and 42 members of the committee were present. A provisional programme of subjects for discussion was agreed upon. This will be published in THE LANCET at an early date.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Medical Men and the Insurance Act.

THE developments in the hostility of medical men towards the Insurance Act are closely watched by Members of Parliament. Many of them have read the proposed Bill framed by the British Medical Association Reform Committee, and it is evident that if the passage of the Act had been delayed for a year the difficulties of the Government in pressing it through would have been very greatly increased. The difficulties have now been transferred from the

legislative to the administrative sphere. That, however, does not mean that the attention of Parliament will be diverted from the struggle going on in the country. On the first day of the session Mr. BONAR LAW, the Leader of the Opposition in the House of Commons, criticised briefly but sharply the London Opera House speech of Mr. LLOYD GEORGE. The passage may be quoted: "Then there are the poor doctors—the poor innocent creatures who do not know their right hand from their left, who know nothing about their own business, and are misled by wily politicians into opposing the beneficent methods of the Chancellor of the Exchequer." Said Mr. BONAR LAW: "It is very interesting. How does the right honourable gentleman now deal with the doctors? The time for cajolery has gone. We all remember that at one stage of the proceedings how every second day inspired paragraphs appeared in the Radical papers to the effect that the eloquence of the Chancellor had squared the doctors. All that has gone now. Blandishment is of no more use, and they are to be brought to heel by threats—I am bound to say by somewhat brutal threats. There are two observations to be made on this question. The first is that the doctors will really be as simple as the right honourable gentleman imagines them to be, if they regard those threats as anything but the wild outburst of impotent rage. Secondly, if he can carry out these threats, which I do not think is possible, then the Insurance Act which will come into operation will be an entirely different measure from the one which went through the House of Commons."

Public Health and Local Administration.

Amongst the Blue-books presented to Parliament in the early days of the session was Part II. of the Annual Report of the Local Government Board for 1910–11. One of the sections relates to public health and local administration. Amongst the many interesting topics with which the section deals are the housing of the working-classes, town planning, infectious disease, hospitals, medical officers of health and their reports, and food- and water-supplies.

Tropical Diseases Research Fund.

The report of the Advisory Committee for the Tropical Diseases Research Fund for the year 1911 is now issued as a Parliamentary Blue-book. The Research Fund has now a revenue of £3345, of which £1000 is received from the Imperial Government. This sum did not quite meet the expenditure of the year, which amounted to £3795 6*s.* 8*d.* It was allocated as follows: London School of Tropical Medicine, £1533 6*s.* 8*d.*; Liverpool School of Tropical Medicine, £1262; University of London, £750; and University of Cambridge, £250. The excess of expenditure over income was met by drawing on the accumulated balance of the Fund. Attention is called by the committee to the urgent necessity of further sums being placed at its disposal in view of the many important questions calling for further research. During the year the committee was consulted on various matters by the Secretary of State for the Colonies, including the appointment of an assistant in the research laboratory at Yaba and the selection of an officer to inquire into the diseases of vomiting sickness and peripheral neuritis which are prevalent in Jamaica. Returns in regard to mosquito-borne disease in various colonies and protectorates have been before the committee, but these are not yet complete. The report states, in conclusion, that the committee notes with pleasure the high standard of work which is being done in various colonial laboratories, and which shows the increased interest in research work which is being taken by the officers in charge. The committee is of opinion tha the experiment of setting up these laboratories has fully justified itself, and that it deserves all possible encouragement.

Industrial Poisoning.

A copy has been presented to the House of Commons of the preliminary tables and cases of industrial poisoning, fatal and non-fatal accidents, and dangerous occurrences in factories, workshops, &c., during the year 1911.

Feeble-minded Persons (Control) Bill.

Amongst the Bills presented by private members in the House of Commons this session is one "to provide for the better care and protection of feeble-minded persons." Mr. STEWART introduced the Bill and it was read a first time. The Prime Minister has promised to deal by legislation with this question during the current session.

The Midwives Act.

As shown by the report of the Central Midwives Board for the year 1910–11 which has just been presented to Parliament, the names on the Midwives Roll on March 31st, 1911, amounted to 31,673, an increase for the year of 2464. Of the total 10,412 had passed the Board's examination and 9655 had been admitted to the Roll in virtue of prior certification under Section 2 of the Midwives Act. The total number of trained midwives was, therefore, 20,067, as against 11,606 untrained, the percentages being 63·4 and 36·6. The corresponding percentages for the previous year were 61 and 39. A large proportion, however, of the trained women do not practise as midwives, and if the number of practising midwives only be considered the untrained women would be found to be in a considerable majority. The number of penal cases dealt with by the Board showed a steady increase, but the report attributes this to the greater thoroughness in administration shown by some of the supervising authorities. The reports of the medical officers of health, it also appears, uniformly bore witness to progressive improvement in the methods of practice of untrained midwives due to the care and assiduity with which the inspectors had instructed and helped those under their charge. The words of the county medical officer of health of Salop are quoted as expressing the universal opinion of those engaged in the administration of the Midwives Act. "Another year of experience," that gentleman reported, "has confirmed me in the opinion that this Act is a measure of the greatest importance, and that the benefit of it will be felt with increasing force from year to year as the untrained midwives are replaced by trained ones." Various points in connexion with the administration and suggested improvement of the Act are discussed in the report.

HOUSE OF COMMONS.

FRIDAY, FEB. 16TH.

The Medical Treatment of School Children.

Mr. HAYES FISHER, in moving an amendment to the motion for an address in reply to the speech from the Throne, drew attention to local taxation. In the course of his speech he asked the Chancellor of the Exchequer to make an interim grant to cover a part of the expenditure on the reduction of the size of classes in metropolitan schools, and also the medical treatment of school children, which, although optional for local authorities, was made a subject of considerable pressure by the Board of Education.

Mr. LLOYD GEORGE, in the course of his reply, said that in regard to the burdens cast by the present Government on the London ratepayer, the feeding of children and medical inspection together did not come to more than £100,000.

Mr. HAYES FISHER: Will the right honourable gentleman deal with the infinitely larger items of medical treatment and Article XIV.?

Mr. LLOYD GEORGE: That is not a burden. It is purely voluntary. It is if the local authorities wish to undertake the responsibility, and personally I should like them to do so. But let me remind the right honourable gentleman that I promised two or three months ago that there should be a subvention to those councils in respect of medical treatment. The right honourable gentleman has overlooked that fact altogether.

Mr. HAYES FISHER: I did not know that the promise had ever been definitely made.

Mr. LLOYD GEORGE: It could not have been more definite. I will just tell those in the House who judge me fairly to wait until they see the education estimates. So far as the cost of medical treatment is concerned the Government has not merely promised definitely to make a subvention to it, but it is on the estimates.

MONDAY, FEB. 19TH.

The Sale of Milk.

Mr. BARNSTON asked the President of the Board of Agriculture whether he was now in a position to state the result of the inquiries which the Board had been making as to the manner in which the existing provisions of the law relating to the sale of milk were at present administered by local authorities.—Mr. RUNCIMAN replied: The inquiries are still proceeding. A considerable amount of information has been obtained, and I am in communication with the Local Government Board as to the steps to be taken to put matters on a better footing.

Food and the Parcel Post.

Mr. TOUCHE asked the Postmaster-General whether precautions were taken to secure that the soft bags now used for the conveyance of parcels, including articles of food, were kept in a clean and sanitary condition.—Mr. H. SAMUEL answered: The reply is in the affirmative. I am advised that bags can be more thoroughly cleaned than baskets.

The Prevalence of Anthrax.

Mr. CHARLES BATHURST asked the Home Secretary to state (1) how many cases of anthrax among human beings occurred in 1911, and how this number compared with those occurring in 1909 and 1910 respectively; and (2) in how many cases during the period of increased prevalence of anthrax among British farm animals in 1911 human anthrax was traceable to contact with such animals or their carcasses or skins, and whether such cases were in excess of those occurring in 1910.—Mr. MCKENNA said in reply: The Home Office is only notified of cases of anthrax occurring in factories and workshops. The number of such cases in 1909 was 56; in 1910, 51; and in 1911, 64. Of these, two in 1910 and one in 1911 were reported to be due to British hides. The Local Government Board, whom I have consulted as to the number of other cases of anthrax, inform me that there are no complete statistics, anthrax in human beings not being generally notifiable, but that the industrial cases referred to above apparently constitute the large majority.

The Care of the Feeble-minded.

Mr. EVELYN CECIL asked the Prime Minister whether it was the intention of His Majesty's Government to introduce a Bill during this session for the better care and control of the feeble-minded on the lines of the Report of the Royal Commission issued in 1908.—Mr. ASQUITH replied: The answer is in the affirmative.

Insurance Act Regulations.

Mr. G. LOCKER-LAMPSON asked the Secretary to the Treasury when the regulations under the National Insurance Act would be issued by the Commissioners.—Mr. MASTERMAN said in reply: I hope in the course of this week to lay on the table of the House regulations prescribing the character of the constitution of unregistered societies seeking approval in accordance with Section 23 (1) of the Act. Other regulations will be laid from time to time as speedily as possible.

TUESDAY, FEB. 20TH.

National Insurance Topics.

Mr. NEWMAN asked the Financial Secretary to the War Office whether, in the event of the National Insurance Act being brought into operation, he could state whether the present privileges with regard to free medical attendance on wives, children, and step-children, as well as on themselves, now enjoyed by army pensioners employed at ordnance factories when residing within one mile of the factory, would

be continued.—Mr. TENNANT replied: The question is under consideration.

The Marquis of TULLIBARDINE asked the Secretary to the Treasury what arrangements were made under the National Insurance Act for providing medical attendance for a contributor who fell ill away from his own locality, as in the case of a Scottish contributor residing temporarily in England.—Mr. MASTERMAN said in reply: It is clearly impossible to state at present what precise form the arrangements will take for dealing with the contingencies referred to in the question. The matter will be for the consideration of the different local Insurance Committees, subject to the regulations and to the approval of the Insurance Commissioners.

Sickness at Osborne College.

Mr. HUNT asked the Civil Lord of the Admiralty whether there were at present at Osborne College two cases of typhoid fever, two of bronchitis, one of pneumonia, and one of diphtheria; whether there were in the College altogether 70 people on the sick list; and, if so, what steps were being taken to prevent the various diseases from spreading.—Mr. LAMBERT answered: There is one case of typhoid fever at Osborne, one of bronchitis, two of pneumonia, and none of diphtheria. On the 18th inst. 72 cadets were on the sick list, almost all suffering from minor ailments. The case of typhoid fever is isolated and the usual precautions are being taken.

WEDNESDAY, FEB. 21ST.

Scottish and Irish Surgeons in England.

Mr. GINNELL asked the President of the Local Government Board whether he was aware of the exclusion of Irish and Scottish surgeons from some surgical appointments in England on the ground of an alleged inferiority of their degrees; if there was real professional inferiority, whether he would say in what it consisted; and, if the allegation was unfounded, whether the Board would withhold its sanction of surgical appointments made subject to the exclusion complained of within the jurisdiction of the Board.—Mr. BURNS said in reply: I am not sure to what appoinments the honourable member refers. Perhaps he will be good enough to communicate with me on the subject. In my department we take no notice of the nationality or religion of the applicants. On their merits only are they appointed.

BOOKS, ETC., RECEIVED.

ALLEN, GEORGE, AND CO., LIMITED, Ruskin House, 44 and 45, Rathbone-place, London, W.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—Resident Medical Officer. Salary at rate of £100 per annum, with board, rooms, and laundry.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Clitheroe, in the county of Lancs; at Frome, in the county of Somerset; at Millbrook, in the county of Cornwall; at Schull, in the county of Cork; and at Staplehurst, in the county of Kent.

Births, Marriages, and Deaths.

MARRIAGES.

MURRAY—HULL.—On Feb. 20th, at St. Gabriel's, Warwick-square, S.W., Captain J. H. Murray, I.M.S., to Freda, daughter of the late Commander T. A. Hull, R.N.
SPROTT—BROSTER.—On Feb. 15th, at St. Margaret's, Westminster, by Canon Hensley Henson, D.D., Ernest W. Sprott, son of the late Walter Sprott, Esq., of Mayfield, Sussex, to Barbara Broster, M.B., B.S., daughter of the late Thomas Mawdsley Broster, Esq., of Liverpool, and Mrs. Broster, of Abergavenny.

DEATHS.

COLLEY.—On Feb. 15th, at Folkestone, Constance Helena Colley, M.D.
DOWNIE.—On Feb. 17th, at Sunny Bank, Cannes, Colonel Kenneth M. Downie, I.M.S., retired, aged 66 years.
JEAFFRESON.—On Feb. 14th, at Red House, Wandsworth, Horace Jeaffreson, M.D., aged 75 years.
KIRBY.—On Feb. 18th, at South Lowestoft, Samuel John James Kirby, M.D., D.P.H., aged 58 years.
MAURICE.—On Feb. 14th, at Lloran House, Marlborough, James Blake Maurice, M.D., F.R.C.S.
OGILVY-RAMSAY.—On Thursday, Feb. 15th, at 5, Portland-square, Carlisle, Maxwell Ogilvy-Ramsay, M.A. St. Andrews, M.D., F.R.C.S. Edin., Hon. Surgeon to the Cumberland Infirmary.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

TWO CROWDED YEARS.

To the Editor of THE LANCET.

SIR,—I suggest that the enclosed is worth publishing in the columns of THE LANCET. I am, Sir, yours faithfully,
Welbeck-street, W., Feb. 16th, 1912. M.B.

ENCLOSURE.

DEAR MR. —— Tottenham, Feb. 7, 1912.

At last I am sending you, our long promised account of how many illnesses we managed to have during two years.

We were at the time 6 (children) in Family. It commenced with Nurse having a M—— Abscess at the back of her ear. Father took her to Golden Square Hospital where she remained for several weeks.

2. Willie, eldest boy, aged 6. Adanoids and Tonsles removed.
3. All, infectious sore throats.
4. Children all Mumps.
5. Mollie & Willie, Measles.
6. Nurse, Scarlet Fever.
7. Nellie, Dorothy and Edie, Measles *and* Scarlet Fever.
8. Arthur (baby then) measles.
9. Nellie, Edie and Arthur, whooping cough.
10. Ringworm and Impetago, all children.
11. Arthur Chickenpox and Impetago.
12. Twins! born (8 of us now).
13. Mollie, Diptheria.
14. General Colds.

I am glad to say at the present time, we are all quite well,
And Remain, Yours Sincerely,
MOLLIE D——.

*** "M.B.'s" young correspondent has contributed a most interesting chapter to medicine. We have left her graphic notes exactly as they were sent to us.—ED. L.

HEALTH AND SANITATION IN NORTHERN NIGERIA.

THE Protectorate of Northern Nigeria, in West Africa, was established in the year 1900, and includes the northern portion of the territories formerly administered by the Royal Niger Company. It is bounded on the south by Southern Nigeria, to the west and north by the French possessions in the hinterland of Dahomey and the Soudan, and on the east by Lake Chad and the German territory of the Cameroons. The area is about 255,700 square miles. In his latest report to the Colonial Office on the affairs of the Protectorate, the Governor, Sir H. Hesketh Bell, K.C.M.G., remarks that in spite of a considerable influx of Europeans, mostly in connexion with the mines, and many of whom have had no previous experience of the tropics, the proportion of deaths and the invaliding rate show a most satisfactory improvement. Greater care in matters affecting health and better precautions as regards exposure and manner of life generally are having a marked effect on medical statistics, and the death-rate of 15·35 per 1000 among the resident European population is the lowest on record since the Government assumed the administration of the territory. The general health of the natives during 1910 appears to have been fairly good, and no epidemic of a serious nature occurred. Leprosy, however, has been found to be terribly rife among the natives of the Moslem states. It is estimated that in the Sokoto Emirate alone there are more than 6000 lepers, and that in the whole Protectorate there are probably some 80,000. The problem is one that requires vigorous action, due consideration being at the same time paid to native susceptibilities. Considerable attention has been paid to sanitation. A senior and junior sanitary officer have been appointed and have already done much excellent work in advising on the measures necessary—including the planning and laying out of new towns and villages—to improve the general health, not only of Europeans, but also of the native communities. Appended to the Governor's report is a summary of the Blue-book of the Protectorate for 1910–11, from which it appears that the average number of Europeans resident in the Protectorate during the year, including officials and non-officials, but excluding those engaged on the Lagos railway (northern extension), was 637, of whom 424 were officials and 213 non-officials. The large increase in the non-official population was due to the extension of the mining industry, and the decrease in the official population results from the reduction of the construction staff of the Baro-Kano railway. The native population is roughly estimated at 10,000,000, but until a careful assessment of land revenue and population has been completed throughout the Protectorate this figure can only be considered as approximate. It will probably prove to be under the actual number.

There were 13 deaths from all causes among Europeans during the year—12 due to disease and 1 to an accident. The total crude

European death-rate, calculated on the average resident population, and not corrected for age and sex, was 20·41 per 1000. The rates from all causes amongst officials and non-officials were 16·51 and 28·17 per 1000 respectively. The number of Europeans invalided during the year was 43. The invaliding rate per 1000 was 73·1 amongst officials and 79·8 amongst non-officials. The general character of the prevalent diseases has been maintained. Malaria still accounts for the greatest number of cases of illness in the Protectorate. The total number of admissions to hospitals of Europeans suffering from malaria during the year was 250, a decrease of 193 cases, notwithstanding that the European population increased from 544 to 637. The number of cases of mortality from blackwater fever was lower by 0·87 per cent. than in the previous year, and by 0·44 per cent. than the average of the last seven years. The actual number of admissions to hospitals on account of blackwater fever was 9 and there were 2 deaths. There was a further increase in the number of natives under treatment at the Government hospitals and dispensaries, the total being 23,770, exclusive of 4951 cases treated by the railway medical staff at Baro. The number of pauper patients treated during the year was 3899, an increase of 432 in the number for the preceding year.

During the year 8 cases of sleeping sickness, all amongst natives, were noted; 1 of these ended fatally. The individuals affected were sent for segregation to a camp in the neighbourhood of Zaria, a district free from tsetse flies. At Baro a marsh extends along the greater part of the river front, but schemes are now under consideration for filling in and draining the ground. According to all the canons of tropical hygiene Baro ought to be a notoriously unhealthy spot. Since its occupation by Europeans, however, its health record has not been at all a bad one, and most of the cases treated in the hospitals there are importations. During the year several cases of trypanosomiasis in natives have been discovered at Baro, and infected persons have been deported to the neighbourhood of Zaria to keep them away from tsetse flies. It is impossible to say if all or any of these cases were importations.

Small-pox is endemic, and takes an epidemic form in some parts of the Protectorate every year. Comparatively few of the cases come under medical observation, but this is not surprising, having regard to the fact that the number of medical officers actually in residence works out at one to an area of 9000 square miles. In some places, too, it is difficult to persuade the natives to agree to vaccination owing to religious or other prejudices. During the year 43 cases, all among natives, were treated, and 3 proved fatal. Successful vaccinations, to the number of 3942 cases, were performed during the year—the majority in the interior of the Protectorate, where formerly scarcely any success had been met with. This success is largely due to the use of powdered lymph. Small-pox is essentially a dry weather disease—every outbreak disappearing with the onset of the rains. Prophylactic inoculation has been practised amongst certain tribes in the Protectorate for many generations. The highest shade temperature recorded in the Protectorate during the year was 114°F. on March 23rd and 26th at two places in the Bornu Province. The lowest shade temperature was 39° at Sokoto on Jan. 4th. The highest mean shade temperature was 84·2° recorded at Baro, and the lowest 76·3° recorded at Ankpa. The greatest range of temperature was 73° recorded at Maiduguri—i.e., 41° to 114°. The greatest total rainfall was 56·44 inches recorded at Ankpa, in the Bassa Province, and the lowest, 16·87 inches, recorded at Geidam, in the Bornu Province. The greatest rainfall in one day was 5·53 inches, recorded at Zungeru on August 6th.

LANTERN SLIDES FOR AMBULANCE LECTURES.

To the Editor of THE LANCET.

SIR,—I should be glad if any of your readers would give me information as to the following: Is there any society or association who will lend lantern slides for illustrating courses of lectures on ambulance work?

I am, Sir, yours faithfully,

Feb. 13th, 1912. H.

MILNE'S SURGICAL DRESSINGS.

DURING Lister's period of work at Edinburgh Mr. John Milne was his special assistant in preparing antiseptic appliances according to the new ideas. When in 1877 Lister came to London he was, we are informed, accompanied by Milne, who established a factory at Ladywell on purpose to manufacture surgical dressings according to the special instructions of the great innovator. The factory has now developed into the Galen Manufacturing Co., Limited.

THE ETIOLOGY OF HERPES.

To the Editor of THE LANCET.

SIR,—The causation and etiology of herpes being somewhat obscure and theoretical, the following case may be of interest. I was asked to see a woman, aged 53, who was complaining of a rash on the arm. On examination she had a typical eruption of herpes on the left arm, extending from the wrist upwards along the inner side of the forearm, arm, and extending on to the chest and back. The eruption on the arm follows the line of the internal cutaneous nerve; on the left side of the chest it is scattered but profuse, and also on the scapular region. The patient is a very "nervous" subject, and the interesting point in the case is this. Three days before she felt the pain which preceded the appearance of the eruption a mouse ran up her left sleeve into her axilla, and was only liberated by her daughter unfastening her blouse at the back. The patient was always terrified of a mouse. I know her statement about the mouse is correct, for her daughter and her husband witnessed the occurrence. I may say I have seen six cases of herpes zoster this week, two of them occurring in two soldiers in the same barrack room.

I am, Sir, yours faithfully,

FREDERICK B. JEFFERISS, F.R.C.S. Edin.,
Chatham, Feb. 17th, 1912. M.R.C.S., L.R.C.P. Lond.

ACCIDENTAL POISONING.

To the Editor of THE LANCET.

SIR,—Might I suggest that all bottles containing poison sold to the public should not only be labelled "poison," but should also bear, in large type, the best means of antidoting such poison when accidentally swallowed? This would be of great use in cases of emergency before the arrival of a doctor.

I am, Sir, yours faithfully,

Fernshaw-road, S.W., Feb. 17th, 1912. (Mrs.) GRACE ROCHE.

"*Practicioner.*"—We think our correspondent, from his pseudonym, is not a practitioner of medicine. Anyhow, there is nothing to be done whatever in the condition.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced for March and April:—

March 7th–11th (Berlin).—Thirty-third Balneological Congress.
March 23rd–April 4th (London, Royal Agricultural Hall).—International Smoke Abatement Exhibition.
April 1st and 2nd (Milan).—Italian National Convention upon the Sexual Question.
" (London).—First Congress of Pure Food and Health Society of Great Britain.
" 1st–7th (Tunis).—Twenty-second Congress of French-speaking Alienists and Neurologists.
" 8th–13th (Rome).—Seventh International Congress of Dermatology and Syphilology.
" 8th–15th (Johannesburg).—Thirteenth South African Medical Congress.
" 9th–11th (Paris).—Congress of Physiotherapy for French-speaking Physicians.
" 9th (Berlin).—Eleventh Congress of the German Society for Orthopædic Surgery.
" 9th–13th (Giessen).—Congress on Study of Families, Inheritance, and Race Hygiene.
" 10th–13th (Berlin).—Forty-first Congress of the German Surgical Society.
" 14th (Berlin).—Eighth Congress of the German Röntgen Society.
" 14th–20th (Rome).—Seventh International Congress on Tuberculosis.
" 15th–18th (Wiesbaden).—Twenty-ninth German Congress for Internal Medicine.
" 21st–24th (Munich).—Twenty-sixth Meeting of the Anatomical Society.
" (London, Olympia).—Ideal Homes Exhibition.

METEOROLOGICAL READINGS.

The following journals, magazines, &c., have been received:—
Journal of Laryngology, Rhinology, and Otology, Birmingham Medical Review, American Journal of Medical Sciences, Bulletin de la Société de l'Internat des Hôpitaux de Paris, Revue de Médecine,

Revue de Chirurgie, Journal of Mental Science, Revue de Psychiatrie et de Psychologie Expérimentale, South African Medical Record, American Journal of Obstetrics and Diseases of Women and Children, Interstate Medical Journal, American Journal of Surgery, Hospital Gazette, British Journal of Dental Science, Crónica Médica, Medical Review of Reviews, American Medicine, Albany Medical Annals, Journal of Tropical Medicine and Hygiene, British Journal of Dermatology, &c.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).

MONDAY.

ODONTOLOGICAL SECTION (Hon. Secretaries—W. W. James, Stanley Mummery): at 8 P.M.

Paper:
Mr. W. W. James: The Dates of the Eruption of Teeth in about 2000 Children under 12.

Casual Communications:
Mr. J. G. Turner: Two Cases of Hypoplasia of Enamel.
Mr. E. Sturridge: An Experiment showing Formation and Migration of Ions.
Mr. J. F. Colyer: Some Radiographs of a Case of Advanced Periodontal Disease.

TUESDAY.

MEDICAL SECTION (Hon. Secretaries—Sir John F. H. Broadbent, Bart., Robert Hutchison): at 5.30 P.M.

Joint Meeting with
SURGICAL SECTION and
SECTION OF ANÆSTHETICS.

Debate:
On a Paper by Mr. T. P. Dunhill of Melbourne: Partial Thyroidectomy under Local Anæsthesia, with Special Reference to Exophthalmic Goitre.

The Debate will be opened by Dr. Hector Mackenzie. The following will take part in the Debate:—Dr. Albert Kocher (Berne), Mr. Wilfred Trotter, Mr. Charters Symonds, Dr. Dudley Buxton, Mr. Donald Armour, Mr. Walter Edmunds, Dr. J. Blumfeld, Dr. H. J. Scharlieb, C.M.G., Dr. G. A. H. Barton, Mr. Rupert Farrant, Mr. H. J. Paterson, Mr. James Berry.

FRIDAY.

LARYNGOLOGICAL SECTION (Hon. Secretaries—W. H. Kelson, Dan McKenzie), at 11, Chandos-street, W.: at 4.30 P.M.

Cases, &c.,
Will be shown by Dr. H. J. Davis, Dr. Watson Williams, Dr. W. H. Kelson, Mr. G. Wilkinson, Dr. Jobson Horne, and others.

SECTION OF ANÆSTHETICS (Hon. Secretaries—Mrs. Dickinson Berry, H. J. Scharlieb, C.M.G.): at 8.30 P.M.

Paper:
Mr. Felix Rood: Ether Infusion Anæsthesia.

Short Communication:
Mr. C. M. Page: Hedona Infusion Anæsthesia.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8.30 P.M., Pathological Evening. Specimens will be on view at 8 P.M.

HUNTERIAN SOCIETY, Guy's Hospital, St. Thomas's-street, S.E.

WEDNESDAY.—4 P.M., Clinical Meeting. Cases of interest will be shown by Dr. G. N. Pitt, Mr. W. A. Lane, and other Members of the Staff of the Hospital.

ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.

WEDNESDAY.—8 P.M., Mr. H. A. Roberts: Education in Science as a Preparation for Industrial Work.

HARVEIAN SOCIETY OF LONDON, Stafford Rooms, Titchborne-street, Edgware-road, W.

THURSDAY.—8.30 P.M., Discussion on Acute Poliomyelitis and Allied Conditions (opened by Dr. F. Buzzard). The following have promised to take part:—Dr. F. E. Batten, Dr. W. d'Este Emery, Dr. T. B. Hyslop, and Dr. L. Guthrie.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

MONDAY, WEDNESDAY, AND FRIDAY.—5 P.M., Prof. A. Keith: Important Phases in the Evolution of Man.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. J. M. H. MacLeod: Clinique (Skin). 5.15 P.M. Lecture:—Mr. J. Cantlie: The Diagnosis and Surgical Treatment of Hepatic Ailments.

TUESDAY.—4 P.M., Dr. P. Stewart: Clinique (Medical). 5.15 P.M., Lecture:—Sir George Beatson, K.C.B.: Treatment of Acute Appendicitis—When and How to Operate.

WEDNESDAY.—4 P.M., Mr. S. Handley: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. F. W. Price: Recent Advances in Heart Disease (illustrated by the polygraph).

THURSDAY.—4 P.M., Dr. E. F. Buzzard: Clinique (Medical). 5.15 P.M., Lecture:—Dr. F. W. Price: Recent Advances in Heart Disease (illustrated by the polygraph).

FRIDAY.—4 P.M., Mr. J. F. Cunningham: Clinique (Eye).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 10.30 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12 noon, Dr. Bernstein: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. R. Lloyd: Administration of Anæsthetics.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 11 A.M., Mr. Etherington-Smith: Demonstration of Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. H. Pritchard: Clinical Pathology.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 10.30 A.M., Surgical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Simson: Diseases of Women. 5 P.M., Lecture:—Mr. Etherington-Smith: Clinical. (Lecture II.)

THURSDAY.—10 A.M., Dr. Simson: Gynæcological Demonstration. 12.15 P.M., Lecture:—Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Baldwin: Practical Surgery. (Lecture V.)

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 12.15 P.M., Lecture:—Dr. Pritchard: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Simson: Extra-uterine Gestation.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. Bishop Harman: Diseases of the Eye. 10.30 A.M., Medical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10.30 A.M., Surgical Out-patient (Mr. E. Gillespie). 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Nose, Throat, and Ear (Mr. H. D. Gillies). 3 P.M., Clinical Pathology and Pathological Demonstration (Dr. W. H. Duncan).

TUESDAY.—Clinic: 2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld).; Surgical (Mr. Howell Evans); Gynæcological (Dr. A. E. Giles). 3.30 P.M., Medical In-patient (Dr. A. J. Whiting). 4.30 P.M., Lecture:—Dr. R. M. Leslie: Arterio-sclerosis and its Treatment.

WEDNESDAY.—Clinics:—2 P.M., Throat Operations (Mr. Gillies). 2.30 P.M., Children's Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen): Eye (Mr. R. P. Brooks). 3 P.M., X Rays (Mr. W. Steuart); Clinical Pathology and Pathological Demonstration (Dr. W. H. Duncan). 5.30 P.M., Eye Operations (Mr. Brooks).

THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 P.M., Medical In-patient (Dr. G. P. Chappel).

FRIDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld): Surgical (Mr. E. Gillespie); Eye (Mr. R. P. Brooks). 3 P.M., Medical In-patient (Dr. R. M. Leslie); Clinical Pathology and Pathological Demonstration (Dr. W. H. Duncan). 4.30 P.M., Lecture:—Mr. R. P. Brooks: Derangements of the Ocular Muscles.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4.30 P.M., Mr. R. Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

TUESDAY.—2 P.M., Operations. 3.15 P.M., Dr. R. Wells: Medicine. 2.15 P.M., Mr. R. Carling: Surgery. 4.15 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin. 4.30 P.M., Special Lecture:—Dr. J. Taylor: Hemiplegia.

WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye. 3.30 P.M., Special Lecture:—Mr. Cargill: Retinitis. 5 P.M., Mr. McGavin: Surgical Demonstration or Lecture.

THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 4.30 P.M., Special Lecture:—Dr. Moon: Cardiac Disease in Children.

FRIDAY.—2 P.M., Operations. 2.15 P.M., Sir J. Rose Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

SATURDAY.—10 A.M., Radiography. 11 A.M., Dr. A. Davies: Pathological Demonstration. 2 P.M., Operations. Out-patient Demonstration:—10 A.M., Surgical and Medical. 11 A.M., Eye.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

THURSDAY.—4 P.M., Lecture:—Mr. Waugh: Abdominal Pain.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

TUESDAY.—3.30 P.M., Clinical Lecture:—Mr. D. Armour: Joint Affection in Nervous Diseases.

FRIDAY.—3.30 P.M., Clinical Lecture:—Mr. P. Sargent: Decompressive Operations.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.

TUESDAY.—6 P.M., Dr. W. Griffith: Bullous Eruptions.

THURSDAY.—6 P.M., Chesterfield Lecture:—Dr. M. Dockrell: Diseases of the Skin Due to Bacillary Infection.

UNIVERSITY OF LONDON (UNIVERSITY COLLEGE), The Francis Galton Laboratory for National Eugenics.

TUESDAY.—8.30 P.M., Dr. D. Heron: A Study of Extreme Alcoholism (Lecture V.)

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C. (in the Lecture Room of the Institute).

MONDAY.—6 P.M., Prof. S. Flexner: The Local Specific Treatment of Infections—The Biological Basis. (Harben Lecture I.)

WEDNESDAY.—6 P.M., Prof. S. Flexner: The Local Specific Treatment of Infections—Experimental Infections. (Harben Lecture II.)

FRIDAY.—6 P.M., Prof. S. Flexner: The Local Specific Treatment of Infections—Epidemic Cerebro-spinal Meningitis. (Harben Lecture III.)

ANCOATS HOSPITAL, Manchester.

THURSDAY.—4.15 P.M., Mr. W. R. Douglas: Renal Calculus. (Post-Graduate Clinic.)

MANCHESTER ROYAL INFIRMARY.

TUESDAY.—4.30 P.M., Dr. Donald: Uterine Fibroids.
FRIDAY.—4.30 P.M., Mr. Wrigley: Demonstration of Surgical Cases.

SALFORD ROYAL HOSPITAL.

THURSDAY.—4 30 P.M., Dr. C. C. Heywood: Serous Pleural Effusion. (Post-Graduate Course).

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (26th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), Central London Throat and Ear (Minor 9 A.M., Major 2 P.M.).

TUESDAY (27th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London, (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.) Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.), Royal National Orthopædic (9.30 A.M. and 4 P.M.).

WEDNESDAY (28th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's 2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), St. Peter's (2 P.M.), Samaritan 9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

THURSDAY (29th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal National Orthopædic (9 A.M. and 3.30 P.M.), Royal Ear (2 P.M.), Children Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

FRIDAY (1st).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Royal National Orthopædic (3.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

SATURDAY (2nd).—Royal Free (9A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.), Hospital operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

The Index and Title-page to Vol. II. of 1911 were given in THE LANCET of Dec. 30th, 1911.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1911 are now ready. Bound in cloth, gilt lettered, price 16*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

Communications, Letters, &c., have been received from—

A.—Messrs. Allen and Hanburys, Lond.; Dr. J. Aikman, Guernsey; Messrs. Arnold and Sons, Lond.; Dr. A. Ashkenny, Birmingham; Automobile Association, Lond.; Mr. George Adkins, Exeter.

B.—Dr. A. E. Brindley, Derby; Bristol Eye Hospital, Secretary of; Bombay Medical Union, Secretary of; Dr. James B. Bird, Carlisle; Major K. Bruce Barnett, R.A.M.C., Bexhill-on-Sea; Mr. E. Bougault, Paris; Bedford County Hospital, Secretary of; Dr. R. A. Barr, Nashville, U.S.A.; Dr. W. Cecil Bosanquet, Lond.; Sir Lauder Brunton, Bart., Lond.; Mr. A. C. Butler-Smythe, Lond.; Messrs. Baillière, Tindall, and Cox, Lond.; Messrs. W. H. Bailey and Sons, Lond.; Major R. J. Blackham, R.A.M.C., Peshawar; Mr. J. Bradock, Manchester; British Medical Association Reform Committee, Lond.; British Medical Benevolent Fund, Lond.

C.—Messrs. J. and A. Carter, Lond.; Mr. H. A. Collins, Croydon; Dr. H. W. Crowe, Yelverton; Messrs. J. and A. Churchill, Lond.; Mr. G. H. Colt, Aberdeen; Mr. Ernest Clarke, Lond.; C. C.; Mr. J. G. Christie, Bloxwich; Cumberland Infirmary, Carlisle, Secretary of; Mr. Thomas Cox, Tredegar; Dr. G. T. Cattell, Ramsbury.

D.—Dewsbury and District General Infirmary, Secretary of; Devonshire Hospital, Buxton, Secretary of; Mr. W. A. Dawson, Preston; Denver Chemical Manufacturing Co., Lond.; Mr. E. Darke, Kingston-on-Thames; Messrs. W. Dawson and Son, Lond.; Mr. Lovell Drage, Hatfield.

E.—Miss Evans, Hyderabad; E. R., Lond.; Egham Urban Sanitary District, Medical Officer of Health of; Mr. A. Elliot-Blake, Bognor; Dr. G. H. Edington, Glasgow; Dr. John Eyre, Lond.

Lettsomian Lectures
ON
GLYCOSURIA.

Delivered before the Medical Society of London.

BY ARCHIBALD E. GARROD, D.M., M.A. OXON., F.R.C.P. LOND., F.R.S.,

PHYSICIAN TO, AND LECTURER ON CHEMICAL PATHOLOGY AT, ST. BARTHOLOMEW'S HOSPITAL; PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN.

LECTURE II.*

Delivered on Feb. 19th.

MR. PRESIDENT AND GENTLEMEN,—It will be remembered that the latter portion of my first lecture was devoted to a discussion of potential or alimentary glycosuria—in other words, to conditions in which tolerance of glucose is depressed below its normal limit, but not so greatly depressed as to be overtaxed by an ordinary diet. The metabolic error present in such conditions is only revealed when an excessive dose of glucose is administered as a test.

I propose to pass on this evening to the consideration of spontaneous glycosuria—that is to say, the excretion of glucose by patients whose diet contains no conspicuous excess of carbohydrate foods. Such glycosuria may occur as a transient phenomenon during a few successive hours or days; may persist for weeks or even months; or again, may be continuous throughout the remainder of the patient's lifetime, unless restrained by restriction of the carbohydrate intake.

TRANSIENT OR TEMPORARY GLYCOSURIA.

Transient glycosuria may result from widely different causes. That due to a toxic substance will cease when the administration of the substance is discontinued, whether it be due to a metabolic disturbance or to a lowering of the retentive power of the kidneys. The glycosuria which results from emptying of the glycogen reservoirs is also transient, and ceases when the reservoirs are empty; and again, glycosuria of brief duration may be due to some temporary derangement of carbohydrate metabolism, owing to causes at work within the organism.

The cases in which such temporary metabolic glycosuria occurs have to be divided into two distinct classes. In the one class may be grouped all those cases in which the tolerance of carbohydrates is continuously depressed and the patient is always on the verge of glycosuria. In such cases spontaneous excretion of glucose will occur when, during some of the fluctuations to which it is liable, the tolerance falls even below its ordinary low level, or whenever some slight excess of carbohydrate food is taken by the patient. Into this group fall the cases of alimentary glycosuria ex amylo referred to in the previous lecture, in which sugar may only be excreted a few hours after breakfast, which is the meal at which most starch and sugar are wont to be taken.

In contrast to such temporary glycosuria, which may be described as the false variety (false, that is to say, as regards its temporary character), is the truly temporary variety, which may also result from disturbance of metabolism as well as from the other causes just referred to, in which, after the urine has contained sugar during a longer or shorter period, tolerance for carbohydrates becomes completely restored. In such cases the recovery is not, as a rule, abrupt, for lowered tolerance for carbohydrates may persist for a time and gradually disappear after the spontaneous excretion of sugar has ceased. It must be pointed out that fluctuations of tolerance are sometimes very wide, and experience teaches that what appears to be a complete recovery is not always permanent.

We have, most of us, met with patients who have assured us that at some previous period of their lives they suffered from diabetes, and were more or less strictly dieted over a longer or shorter period, but who have long discarded all restrictions of carbohydrate foods, and nevertheless exhibit no symptoms of diabetes, and no longer excrete any sugar.

Such evidence, although it is far too incomplete to afford scientific proof, serves to create the impression that a few sufferers from a diabetes of some duration do actually recover completely. Many recorded instances serve to strengthen this impression, and a very small number have been studied with sufficient accuracy and completeness to carry conviction. It is astonishing how few such cases are really conclusive. As a rule, the records are deficient in evidence either that the reducing substance excreted in the urine was actually glucose, or that there was a complete recovery of carbohydrate tolerance after the glycosuria ceased; and many others have not been followed up for any considerable period after that event.

Teschemacher [1] has described the case of a man, aged 57, who was first seen by him in the summer of the year 1899. Sugar had been found in his urine six months previously, and the diagnosis of mild diabetes had been made. After a course of treatment at Neuenahr, together with appropriate restrictions of diet, he ceased to excrete sugar, and although he resumed an ordinary diet soon afterwards, there was no return of the glycosuria. His urine was examined at intervals, short at first and longer later, up to the time when, no less than ten years afterwards, he again came under Teschemacher's care with albuminuria, high pulse tension, and dilatation of his hypertrophied heart. The albumin had first been detected in his urine at one of the periodic examinations in 1906, but at no such examination had glucose been found. I know of only one instance in which the period of observation after recovery has been more prolonged.

A case recorded by Hürter [2] in 1910 is that of a girl, 10 years of age, whose parents were healthy, but some of whose kinsfolk had suffered from diabetes. In July, 1908, she had suffered from an intestinal catarrh, accompanied by urticaria, which had attacked two other members of her family at the same time. There had been several recurrences of the intestinal symptom since. Four weeks before the child came under observation she had suffered from an attack of vomiting after a slight indiscretion of diet, and from that same day had suffered from excessive hunger and thirst; the urine was often abundant, and she had lost flesh. Sugar was detected in her urine in the third week of the illness. Physical examination revealed nothing amiss in the child's abdomen, or nervous system, but the urine contained no less than 9 per cent. of glucose, and yielded a feeble ferric chloride reaction. As the sudden onset suggested an acute affection of the pancreas Schmidt's test diet was given, and his silk bag test was applied, but no evidence of pancreatic disease was thereby afforded. The patient was strictly dieted, and the output of glucose fell from 210 grammes to 5 grammes in the 24 hours, and after several days of vegetable diet the glycosuria ceased in a little more than a week after the commencement of dietetic treatment. On a single occasion, some ten days later, the reactions of sugar were again obtained. Seven months later the child had gained 6 kilogrammes in weight, all the symptoms had disappeared and there had been no recurrence of glycosuria. Moreover, the taking of 420 grammes of white bread caused no excretion of sugar, and a dose of 50 grammes of glucose was equally without effect. Since then the patient had returned to an ordinary diet, and the urine had remained sugar-free.

This case has been quoted at length because it is specially remarkable in several respects. In the first place, because the patient was a child, and it is a familiar fact that the prognosis of diabetes in children is especially sinister; secondly, because of the very large output of glucose, which was comparable to that seen in the gravest diabetic cases; and thirdly, because of the recovery of tolerance after the attack. All that is to be wished for is a longer period of after-observation, a gap in the evidence which lapse of time may supply. The case is also of special interest because of the association of the temporary diabetes with gastro-intestinal disturbance, a subject to which I shall have occasion to return later.

The necessity of caution in pronouncing that a patient has actually recovered, unless prolonged observation has followed, is well exemplified in a case described by Leo [3] of a man aged 31, who between 1901 and 1904 developed diabetes with polyuria and thirst on three separate occasions, and whose urine contained at times as much as 6 per cent. of glucose. In one of the sugar-free intervals he had so completely

* Lecture I. was published in THE LANCET of Feb. 24th, 1912, p. 483

[1] Deutsche Medizinische Wochenschrift, 1910, Band xxxvi., p. 401.
[2] Medizinische Klinik, 1910, Band vi., p. 140.
[3] Berliner Klinische Wochenschrift, 1904, Band xli., p. 1293.

recovered his carbohydrate tolerance that he was able to take a test meal of 400 grammes of bread, 500 grammes of potato, and 100 grammes of sugar without inducing glycosuria. This was in the month of July, and yet by the following October the diabetic symptoms had reappeared.

I will refrain from quoting other cases here as I shall have to refer to some such later, including one of no small interest which has been under my own observation for two years past.

Although temporary glycosuria of slight degree is not very uncommon, there can be no question that the impression that diabetes, once established, is permanent, is justified in the immense majority of instances. In some cases, at least, this malign tendency is attributable to the permanent character of the underlying disease upon which the disturbance of carbohydrate metabolism depends, as, for example, a chronic fibrosis of the pancreas. On the other hand, the conspicuous influence which dietetic treatment exerts upon the course of the malady, and the great recovery of tolerance of carbohydrates which often results from a period of strict dietary, seem to show conclusively that to work the damaged machine is to aggravate the damage, whereas if the mechanism be rested for a time it tends to recover some of its lost efficiency.

This raises a question of the greatest interest, to which no definite reply can yet be given—namely, whether or no a glycosuria, that has its origin in a lesion which is itself of a temporary character and admits of recovery, can be rendered permanent by neglect of dietary restrictions during the active period.

Undoubtedly recovery takes place in some cases of glycosuria in which no restriction of the carbohydrate intake has been imposed during the glycosuric period; but it appears to me that there are sufficient grounds for suspecting that the answer to the above question should be in the affirmative, to cause us to act upon that assumption in our capacity as practical physicians. In matters of health and sickness, of life and death, we cannot always afford to wait for scientific proof before adopting therapeutic precautions which we feel confident will do no harm.

The Diabetic Tendency.

Closely akin to this question is that of the diabetic tendency. There can be no doubt that members of certain races—for example, of the Jewish race—are more liable to diabetes than other men, and I think that certain colourings of hair and skin, which are probably racial indications, are specially common among diabetic patients. Again, in some instances, the hereditary tendency is so pronounced as to admit of no question. Are we to suppose that in some people carbohydrate metabolism is, so to speak, in a condition of unstable equilibrium, so that it is more easily upset, and when upset recovers itself less readily than in the majority of the human race?

If, as some now think, the internal secretion of the pancreas be controlled by balanced influences emanating from other glandular organs, such as the thyroid and pituitary body, the above conception is more easily entertained.

On the other hand, it must be remembered that certain organic lesions, such as granular kidney and arterio-sclerosis, are to some extent hereditary, and that the disturbance of carbohydrate metabolism which attracts our notice may be merely the result of underlying lesions, the tendency to which is transmitted in certain families and in certain races.

SHARE OF VARIOUS ORGANS IN CAUSATION.

Such considerations lead, by an easy transition, to the introduction of my main theme—namely, the share taken by various organs of the body in the causation of glycosuria.

If I may be permitted to lay before you, at the outset of this discussion, a rough sketch in outline of the conception of this subject which has been in my mind when framing these lectures, and which is doubtless largely derived from the study of the writings of Falta and his fellow workers in von Noorden's clinic, it will take some such shape as this.

We may conceive of a group of enzymes carrying on the actual work of the metabolism of carbohydrates, as of other branches of metabolism. We may picture to ourselves the glands of internal secretion as directing, controlling, and supervising the work of the enzyme labourers, now restraining their activity, and now stimulating them to increased exertions. Of the several glands concerned in this work, among which the pancreas stands pre-eminent, we may conceive of some as helping and some as hindering the actions of others, so that, if the influence of one of them be withdrawn, or be too powerfully exerted, the balance normally maintained is overthrown and disorder results. Lastly, we may picture these overseer glands as themselves controlled by a still higher authority resident in the nervous system, for the influence of the nervous system upon the glands of internal secretion hardly admits of doubt.

This is nothing more than a working hypothesis, but there is much which may be adduced in support of some of its contentions, and it is difficult to frame an alternative hypothesis which fits in so easily with many ascertained facts. If it contain any stratum of truth, it may indicate why it is that glycosuria occurs as a symptom of so many different morbid disturbances, and, to some extent, why its occurrence is apparently so capricious.

Glycosuria and the Nervous System.

The influence of the nervous system upon the metabolism of carbohydrates is manifested in various ways. We can all of us testify to its influence upon the course of diabetes, for we have seen cases in which mental worry, overwork, or shock has been responded to by an obvious aggravation of symptoms, whereas when these factors are removed the malady may resume its ordinary course. Again, there are many well-authenticated cases in which diabetes of a severe kind, persisting up to the death of the patient, has developed after a severe psychic shock or after an injury to the head. I do not propose to quote records of such cases, an admirable series of which will be found in the great works of Naunyn[4] and of Lepine[5] on diabetes mellitus.

Again, cranial injuries and also psychic disturbances may induce transient glycosuria lasting only for a day or two, or at most for a few days, and the same is observed in not a few cases of cerebral hæmorrhage and sometimes after epileptiform convulsions. Examples of both these latter varieties have come under my own observation during the past few weeks. There is much to suggest that such transient glycosurias are of the same nature as "puncture" glycosuria and result from emptying of the glycogen reservoirs under the influence of the centre in the floor of the fourth ventricle.

There is reason to believe that a similar effect may follow a variety of more or less violent "insults" to the organism, and that the transient excretion of glucose which has been observed after severe traumata which do not involve the head; after operations abdominal and other (although in this connexion the possibility of anæsthetic glycosuria has to be taken into account); after ligature of the bile-ducts in animals, and in association with attacks of gall-stone colic, belongs to this same class.

So great has been the influence of Claude Bernard's discovery on the views of the profession upon such matters that it has been assumed that in most of the cases in which cerebral lesions, such as hæmorrhages, tumours, and meningitis, have been followed or accompanied by glycosuria, this has been due to an implication of the glycosuric centre. In some instances there has been evidence of such extension, but in many cases there is none, and it is uncertain whether a persistent glycosuria is ever attributable to a lesion of the glycosuric centre.

It is probable that the excretion of sugar in cases of gross lesions of the brain and spinal cord may be induced in several different ways. Sometimes it may result from disturbances of internal secretion, and it is possible that in the same way as a violent psychic disturbance may be followed by the development of exophthalmic goitre, such a disturbance may, by way of a similar mechanism, excite glycosuria. Nor must we forget that attached to the brain is a gland of internal secretion, the pituitary, which undoubtedly takes part in controlling carbohydrate metabolism. Again, nervous lesions sometimes result from diabetes, and it is important to exclude from consideration all cases in which it is probable that the glycosuria may have been in existence before the development of symptoms referable to the nervous system.

In this connexion, let me select for special consideration a variety of glycosuria which has interested me of late—namely, that which occurs in the course of tuberculous meningitis. That sugar is occasionally present in the urine

[4] Der Diabetes Mellitus, second edition, 1906.
[5] Le Diabète Sucré, 1909.

n cases of meningococcal meningitis has long been recognised, and examples have been recorded by Mannkopf,[6] Emil Adler,[7] and others; but I have never met with it in an undoubted case of the post-basal meningitis of infants. The glycosuria of tuberculous meningitis, on the other hand, has passed almost unnoticed, although its occurrence has been mentioned by Loeb,[8] by Still,[9] and by Aldren Turner and Grainger Stewart.[10] Yet it is present in more than 30 per cent. of all cases of the disease, as some observations which I have carried out in association with Dr. R. S. Frew, at the Hospital for Sick Children, show.

As a rule, sugar appears in the urine only during the last week of life, and usually during the last two days. The urine reduces Fehling's solution readily, the reducing substance present has repeatedly been proved to be glucose by its optical properties, fermentation by yeast, and the characters and melting point of the osazone. The quantity is usually some 0·3 per cent., and seldom greater than 1 per cent.

Careful examinations which Dr. Frew has carried out of the distribution of the meningitis, in the cases with and without glycosuria respectively, lend no countenance to the idea that the glycosuria is due to the approach of the inflammatory changes to the glycosuric centre; but the influence thereupon of the internal pressure of the accumulated cerebro-spinal fluid, the internal hydrocephalus, is a factor which hardly admits of estimation. Nor do the anatomical findings lend support to the suggestion, which Loeb put forward, that the implication of the pituitary gland is concerned in the production of the glycosuria.

A third possible explanation is that the glycosuria of tuberculous meningitis is of the asphyxial variety. It is apt to appear at the period when the respirations become shallow and grouped, with periods of apnœa, conditions which may well favour imperfect ventilation and accumulation of carbon dioxide in the lungs and tissues. Thus the excretion of sugar in tuberculous meningitis offers a good example of the fact that there are various possible explanations of this symptom when it occurs in association with lesions of the nervous system, and illustrates the necessity of caution in drawing sweeping conclusions from such associations.

Glycosuria and Diseases of the Pancreas.

The connexion between diseases of the pancreas and the excretion of sugar in the urine, which has long been suspected on clinical grounds, was proven by the experimental researches of Minkowski and by his demonstration that complete removal of that gland was, in the case of dogs, followed by a grave form of diabetes. The question is no longer whether the pancreas has a share in the causation of diabetes, but how great that share may be. It is difficult to offer any other explanation of the observed facts than that the pancreas produces an internal, as well as the external secretion which plays so important a part in digestion. The available evidence points strongly to those groups of cells which are known as the islands of Langerhans as the structures which produce the internal secretion, for the view that these are not distinct structures, but rather exhausted portions of the glandular tissue, has not met with any wide acceptance.

If the accepted view be correct, we must look upon the pancreas as having, disseminated through its structure, a gland of internal secretion, and, seeing how small a portion of such a gland, so long as it remains functionally active, is able to carry on its work, it is not surprising that a removal of pancreatic tissue which falls far short of completeness fails to induce diabetes in a dog, nor that in many cases grave disease of the gland fails to cause glycosuria. Indeed, as we might expect, diseases of the pancreas which are themselves of less grave kinds, but produce widespread tissue changes, are the most apt to disturb the metabolism of carbohydrates.

The diagnosis of diseases of the pancreas presents great difficulties. The gland is so deeply seated that for the recognition of its slighter maladies we are compelled to rely almost entirely upon circumstantial evidence, and such evidence relates chiefly to the adequacy of its external secretory activity. Hence our views as to its pathology have acquired an unduly lurid aspect, and are based largely upon acute hæmorrhagic pancreatitis, necrosis, obstruction of the duct by calculi, and carcinoma which is especially apt to develop in the head of the gland.

Carcinoma of the pancreas gives rise to a group of symptoms which suffice, in most cases, for its accurate diagnosis. Pain and palpable swelling are met with in cases of acute inflammation, but the symptoms are often ambiguous, and not infrequently the correct diagnosis is only made upon the post-mortem table.

Glycosuria with hyperglycæmia is the only known symptom of failure of the internal secretion, and hence this symptom is of little value for the proof of its own origin. Only when it is attended by indications of associated failure of the external secretion can a pancreatic origin be more than suspected.

Although it is an arguable proposition that the internal secretion of the pancreas is the sole controller of carbohydrate metabolism, and that it is always concerned in the causation of what I have spoken of as metabolic glycosuria, there can hardly be any question that actual disease of the pancreas is not the primary cause of all such glycosuria, but rather that in some cases the assumed influence of the pancreas is secondary, its internal secretion being itself controlled by those of other organs.

In carcinoma of the pancreas glycosuria is an uncommon symptom, as we should expect, seeing that the growth is usually so localised, but Miraille,[11] who collected records of 50 cases, found this symptom noted in 13, as against 37 in which it was absent. In two of the 37 cases in which there was no spontaneous excretion of sugar, there was lowering of tolerance for glucose. In a case which came under Miraille's own observation glycosuria was present for a time, but ceased some two months before the patient's death, and he states that an interval as long as 11 months had been observed between the cessation of glycosuria and the death of a patient.

Glycosuria is also rare in cases of grave pancreatitis, Brentano[12] has described a case of necrosis and sloughing of the gland, in which a subdiaphragmatic abscess was opened. The patient eventually recovered and left the hospital with a pancreatic fistula and with persistent diabetes. Strube[13] also observed glycosuria, which ceased a few days before death, in a fatal case of necrosis. Marwedel has recorded[14] a case of abscess of the pancreas in which sugar was excreted during a few days only.

Benda and Stadelmann[15] found 3 to 5 per cent. of sugar in the urine of a patient who succumbed to hæmorrhagic pancreatitis with fat-necrosis, in whose previous history there had been nothing to suggest an antecedent diabetes; and in 1901 Mr. Gifford Nash[16] observed areas of fat-necrosis in a case in which he operated for gall-stones. The patient recovered, and during convalescence the sugar which had been present disappeared from the urine. However, Mr. Mayo Robson[17] supplies the further information that in 1902, 1904, and 1906 sugar was again found in small amounts, and Cammidge's reaction was on each occasion positive.

In association with pancreatic calculi, also, diabetes has repeatedly been observed.

We are justified in supposing that the pancreas, like the salivary glands, is the seat of inflammatory affections of an altogether milder kind, and which do not manifest themselves by any unequivocal localising symptoms. Naturally we know little of such forms of pancreatitis, for they are little likely to bring about the death of those who suffer from them. Such information as we possess is chiefly derived from laparotomies, during which swelling or undue hardness of the gland may be detected by the finger of the surgeon. I am now speaking of inflammatory troubles in the pancreas which admit of recovery, for fibrosis of the gland, which may be one of the sequels of such troubles, is a familiar post-mortem finding.

Some additional aid in diagnosis may be afforded by the effect of pressure exerted by the swollen head of the pancreas upon the common bile-duct, and, just as deep jaundice due to complete biliary obstruction is one of the most conspicuous symptoms of pancreatic carcinoma, so also we may well imagine that jaundice may result from inflammatory swelling of the head of the gland.

Oser, writing in 1898,[18] suggested that some cases of catarrhal jaundice may be so produced by a transitory swelling of the head of the pancreas, and Mr. Mayo Robson[19] has expressed still more boldly his belief that many cases of transient jaundice admit of such an explanation. However, the pancreatic and biliary ducts are so close together that it is quite as probable that they may both be simultaneously affected by an extension of catarrh from the duodenum into which they open.

We may also well imagine that a catarrhal inflammation of the pancreas may give rise to glycosuria, although it may cause little interference with the external secretion of the gland, and that, as in other pancreatic diseases, excretion of sugar will be the exception rather than the rule.

The following case may well have had such an origin :—

A man, aged 58, came under my observation in the out-patient department of St. Bartholomew's Hospital in October, 1909. He exhibited a moderate degree of jaundice, which had been first noticed three days previously, and at the same time had begun to complain of thirst. Cutaneous itching had been noticed for seven days. He stated that his appetite had been poor for ten weeks previously, and that for four weeks he had felt weak and had been losing flesh. He had experienced no pain, and gave no history of anything resembling gall-stone colic. His motions had tended to be loose for years, and his bowels had been moved two or three times each day. His only previous illness had been an attack of bronchitis two years before. He was admitted to the hospital under my care on Oct. 29th, 1909.

On admission it was noticed that the patient's tongue was slightly furred. His liver was enlarged, and reached four fingers breadth below the costal margin. There was no tenderness in the region of the gall-bladder, which was not palpable. His skin and conjunctivæ were jaundiced, but his motions were not very pale. Nothing abnormal was found in his chest, save a slight degree of emphysema of the lungs. The patient was fairly well nourished. His urine, which was bile-stained, was found to contain a reducing substance, which was proved to be glucose, in a quantity amounting to 2·8 per cent. as estimated by the dextro-rotation. The urine contained no albumin, and did not yield the reactions of acetone nor diacetic acid. The total volume of urine passed in 24 hours varied between 570 and 1285 c.c.

It was thought probable that, in spite of the absence of pain and of tenderness or enlargement of the gall-bladder, the patient might be suffering from gall-stones, which had set up a pancreatitis. Cammidge's reaction gave a negative result, but it is much to be regretted that the various other tests of the pancreatic functions were not applied in this case. Shortly after the patient's admission it was noticed that the jaundice was passing off, and by Nov. 16th all traces of it had disappeared, as in cases of simple catarrhal jaundice. There was never any pain or vomiting, and the temperature did not rise above the normal during his stay in the hospital.

The carbohydrates of his diet were gradually reduced; protene and casoid bread were substituted for ordinary bread, and eventually he was put upon a strict diet, save that he was allowed small quantities of milk. However, sugar, although reduced in amount, continued to be present in his urine. His weight remained practically unaltered.

The sugar estimations are embodied in the following table :—

Date. 1909	Volume of urine in 24 hours. c.c.	Percentage of sugar.	Total output of sugar. Grammes.
Nov. 1st	1171	3·6	42·15

[18] Nothnagel's Handbuch, vol. xviii., Theil 2, p. 111, 1898.
[19] Loc. cit., sub. 17.

On Dec. 7th the diet was relaxed, preparatory to his leaving the hospital, by the addition of 2 ounces of white bread, and on Dec. 10th the allowance of bread was increased to 4 ounces.

On Dec. 31st, 1909, the patient presented himself in the out-patient department. He had kept to the diet prescribed as far as he had been able, and for the first time a specimen of urine which he brought with him contained no sugar. On Jan. 14th, 1910, as there was still no sugar in the urine which he passed at his visit, nor in that collected at an earlier time in the day, the allowance of bread was increased to 6 ounces. On Jan. 28th there was still no glycosuria, and on Feb. 4th sugar was still absent, although he had taken an unrestricted diet for a week. A fortnight later, after a diet rich in carbohydrates, including sugar, several specimens were examined and were still sugar-free.

Since then repeated examinations have always failed to detect sugar in his urine, and the patient has now kept free from glycosuria for two years, although he has discarded all restriction of carbohydrates, and has taken some 14 ounces of bread in the day, in addition to other starchy foods. On Sept. 17th, 1911, he came into hospital for a night. On the morning of the 18th he took 100 grammes of glucose, fasting, but no sugar was found in the urine passed during the succeeding 12 hours.

Here we are confronted with an example of complete recovery of carbohydrate tolerance, a recovery which has been maintained for two years, by a man who, during two months at least, exhibited a glycosuria of moderate degree, which, whilst it lasted, was greatly diminished, but never removed by restriction of diet. Although there was no polyuria whilst he was in the hospital, the name diabetes can hardly be refused to the condition which was at that time present.

It must be acknowledged that the evidence of a temporary affection of the pancreas is very far from complete, although the association of the glycosuria with catarrhal jaundice is certainly suggestive. I do not attach very great weight to the negative outcome of Cammidge's test in this instance; for although I believe that this test, if performed by one thoroughly accustomed to the technique, and taken in conjunction with other tests, and especially with estimations of the total fat and unsplit fat in the stools, affords valuable aid in the diagnosis of pancreatic disease, its indications, especially when negative, are not regarded by most observers as in themselves conclusive. The case serves to illustrate the importance of trying all available tests, even in cases which do not, at first sight, promise an unusual outcome; for its value to the study of temporary diabetes would have been immensely enhanced had the tests of pancreatic efficiency been carried out in the early period.

Even as it stands it shows that the prognosis of diabetes is not necessarily hopeless, although the possibility of relapse cannot even yet be excluded.[20]

There is one variety of transitory pancreatitis known to us which is of special interest in connexion with the subject under discussion—namely, that which occasionally occurs as a complication of mumps. The clinical evidence that the affection so diagnosed is really a pancreatitis is very strong. The symptoms develop as the parotitis subsides, in the peculiar metastatic manner, which is a familiar feature in connexion with other glands, such as the testis and mamma, and is suggestive of a similar glandular inflammation. The abdominal pain, with tenderness, or even swelling in the region of the pancreas, and the subsidence of the acute symptoms in the course of a few days, recall the clinical features of the primary parotitis. With it are often associated intestinal disturbances, such as diarrhœa.

In a case which Finizio[21] has recently placed on record, the patient, a child, aged 11 months, developed, about a week after the appearance of mumps, abdominal pain, epigastric tenderness, vomiting, and diarrhœa. After a few days the pain became less severe, but vomiting continued, and the fæces, which had a very offensive odour, contained large quantities of neutral fat. A chemical analysis showed that some 60 per cent. of the fat was unsplit, as is the case

[20] Since these words were written I have again seen this patient and examined three specimens of urine, passed in the early morning, at 1.30 P.M., and at 2.30 P.M. respectively. The first and last specimens did not reduce Fehling's solution at all, but that passed at 1.30 reduced feebly, and yielded a crystalline osazone which melted at 206°. The saving clause is therefore regrettably justified.
[21] La Pediatria, 1909, vol. xvii., p. 674.

in the steatorrhœa which sometimes accompanies pancreatic diseases. In the course of a month the fæces gradually regained their normal character, and the infant made a complete and satisfactory recovery. The occurrence of such stools, when taken in conjunction with the other symptoms mentioned, afforded very strong evidence of the presence of an inflammation of the pancreas, the benign nature of which is what might be expected in a lesion associated with mumps.

Dr. P. J. Cammidge, who has examined the urine of eight patients with abdominal symptoms suggestive of this form of pancreatitis, has been kind enough to let me have the results of his examinations. In four cases the pancreatic reaction was positive, and in one of these a second examination, after an interval of a month, gave a negative result.

On the other hand, as far as I am aware, no one has ever yet seen the inflamed pancreas in such a case. We do not know what portion of the gland is chiefly affected, although the analogy of the other manifestations of the disease would lead us to expect that the entire pancreas would be involved and would be tensely swollen. The abdominal symptoms certainly indicate a far more acute pancreatitis than that which is suggested as the cause of many attacks of catarrhal jaundice.

Yet a somewhat extensive search through the literature of this subject has not brought to my notice any case in which jaundice has accompanied the pancreatitis of mumps, and in the records of many of the cases, even including Finizio's case with steatorrhœa, it is expressly stated that the urine contained no sugar. Indeed, I had almost come to think that one would be justified in asserting that this form of pancreatitis is never accompanied by glycosuria, when I lighted upon a case described by Vico Barbieri[22] in 1909 which shows clearly that no such sweeping assertion can be made.

Barbieri's patient was a boy, 6 years of age, who acquired mumps in the midst of an epidemic of that disease. Six days after the onset he complained of continuous pain above the navel, which radiated round into the right lumbar region, and he suffered from vomiting and diarrhœa. When the child was first seen the pain had persisted for four days; there was still some swelling of the right parotid gland, but it was no longer painful. There was tenderness in the epigastrium, in the middle line, two fingers breadth above the umbilicus. The temperature was slightly raised; the fæces were pale and showed many fat globules. The urine, which amounted to 2400 c.c. in 24 hours, had a specific gravity of 1034, was free from albumin, but reduced Fehling's solution and yielded Nylander's test. Unfortunately circumstances prevented estimation of the sugar. About a fortnight later all the symptoms had disappeared and the glycosuria had ceased. The daily output of urine had fallen to 600 c.c. and its specific gravity to 1015.

In one of Dr. Cammidge's cases above referred to sugar was found in the urine when the pancreatic reaction was obtained, but was absent a month later when the pancreatic reaction had also ceased.

In 1899 A. F. Harris[23] described a case of diabetes mellitus in a man, aged 42, in which sugar had been first found in the urine a month after an attack of mumps, and mentioned that he had seen in literature several references to the effect that diabetes has not infrequently followed mumps, but he does not give any references.

We must conclude that in exceptional cases the pancreatitis of mumps is attended by glycosuria, which may cease as the pancreas regains its normal condition, but that possibly lasting diabetes occasionally results. The most important point is that recovery from a pancreatic glycosuria may occur.

There is important evidence that in certain suitable cases operative interference at an early stage may avert irreparable injury to a damaged pancreas, and may arrest glycosuria. Reference has already been made to Mr. Gifford Nash's case, but in it the pancreatic lesion was of a grave kind, and the glycosuria was not permanently arrested.

In 1907 Mr. Mansell Moullin[24] recorded the case of a middle-aged woman admitted to hospital with cholecystitis and cholangitis, and who had suffered from biliary colic 11 years previously. The urine had been repeatedly examined in October, 1906, but the notes of that time made no mention of glycosuria. On her admission in 1907 it had a specific gravity of 1050, and contained glucose to the amount of 7 per cent. An operation was performed on April 16th, and gall-stones were removed; the pancreas was felt to be firm, but not sufficiently so to suggest a chronic pancreatitis. After the operation the sugar diminished progressively, and by May 4th had completely disappeared from the urine. Here the period of observation was too short to show how far recovery was permanent.

In a recent very suggestive lecture delivered by Mr. Mayo Robson[25] in 1910, he describes cases in which glycosuria ceased after operations, including examples of carcinoma of the head of the pancreas secondary to carcinoma of the bile-ducts; cases of biliary calculus in which the pancreas was found to be swollen at the time of operation; of duodenal ulcer with cholangitis and interstitial pancreatitis; and of catarrhal pancreatitis with gall-stones. In conclusion, he urges that each case of glycosuria should be considered from the point of its etiology, seeing that certain cases of glycosuria of pancreatic origin are curable, and that in others the progress of the disease may be arrested by suitable surgical measures, which can be carried out with little risk to the patient.

Of all diseases of the pancreas chronic interstitial pancreatitis is that which is most often found post mortem in cases of diabetes, and, conversely, that which most commonly gives rise to glycosuria. Opie,[26] who has made a special study of this subject, describes two varieties of interstitial pancreatitis—namely, an interacinar variety in which the newly formed fibrous tissue is distributed through the lobules of the gland and between the acini, with the result that the islands of Langerhans become early involved; and an interlobular variety in which they only suffer at a late stage. The change induced in the islands is of the nature of a hyaline degeneration. Other observers, and among them Weichselbaum,[27] have found the islands of Langerhans to be reduced in numbers, and to have undergone structural changes, in most fatal cases of diabetes mellitus.

The fibrotic changes referred to may be due to extension from the biliary ducts, as in gall-stone cases, or may apparently result from infection from the alimentary tract. Again, G. Hoppe Seyler[28] has shown that fibrosis of the pancreas may occur in association with generalised arterio-sclerosis and fibrosis of other organs, and that in this way may be explained the cases in which diabetes originates in later life in association with granular kidney and gout.

Glycosuria and Hepatic Diseases.

Seeing how important a part the liver plays in carbohydrate metabolism, we should be surprised to find how insignificant a share diseases of that great laboratory gland appear to take in the causation of glycosuria, were it not that experience teaches us that the same holds true for other metabolic processes of which it is the seat.

It is true that glycosuria often occurs in clinical association with morbid changes in the liver, and some authorities—including Naunyn and Saundby[29]—consider that cases of hepatic glycosuria form a definite group; but in some cases, and perhaps in the majority, the association is to be explained by extension of the morbid process to the pancreas. Such an explanation may well apply to the examples of glycosuria with ordinary hepatic cirrhosis, although Naunyn has met with such cases in which the pancreas showed no signs of morbid change, and it is certainly true of the rare and remarkable cases with hæmochromatosis, known by the name of "bronzed diabetes."

To the same cause may be assigned the not uncommon development of glycosuria in association with chronic cholelithiasis, whereas the transitory excretion of sugar during paroxysms of gall-stone colic, described by Gans[30] and others, has the characters of "puncture" glycosuria.

As we have already seen, even lowering of glucose tolerance is not a special feature of hepatic diseases.

Glycosuria with Intestinal Disorders.

The occurrence of glycosuria in connexion with diseases of the alimentary tract has only recently attracted much attention, and we know little about it as yet. But it promises to provide fruitful lines of inquiry and holds out hope of therapeutic advances.

It is a point worth noticing that in some of the most convincing cases of recovery from diabetes there have been associated gastro-intestinal disturbances, as, for example, Hürter's case of a child of 13, already referred to, and one of the often quoted cases of Richard Schmidt.[31] A child of 4 years, whose mother and elder sister were diabetic, and whose urine had been repeatedly examined and had been found to be free from sugar only four days previously, was attacked by an acute "gastric fever," in association with which the specific gravity of the urine rose to 1042, and it was found to contain 5·8 per cent. of sugar. A rigid diet was initiated and the sugar disappeared after 17 days and never reappeared, although the patient had been under Schmidt's observation for no less than 20 years from that time and had taken an unrestricted diet.

Karl Funck,[32] who is the pioneer in the field, has recorded the case of a man, aged 33, who stated that he had lost flesh for a year, had suffered from polyuria and pruritus, and had been known to excrete sugar for six months. During his illness his stools had almost always been very loose, and the diarrhœa had increased since he had taken a diabetic diet. The loose stools were not fatty, and the fermentation test for a pancreatic lesion gave a negative result. In the mornings his urine had little reducing power, but that passed in the afternoon contained 1·8 per cent. glucose, no albumin, and no indican. His diet was readjusted with a view to his colitis. On a constant diet the sugar gradually diminished, and on the twenty-sixth day of treatment no specimen contained any. Two months later 60 grammes of glucose failed to excite glycosuria.

In a second case three successive attacks of mucous colitis were each associated with glycosuria, which ceased in the intervals. In both cases the sugar disappeared from the urine without restriction of carbohydrates, and in both Schmidt's test of pancreatic efficiency and Cammidge's test gave negative results.

Richartz[33] has recorded a somewhat similar case of a man of 60 years, whose father and brother had died of diabetes. He himself had excreted sugar in 1901, and at that time also the transient glycosuria had been associated with diarrhœa. With a fresh attack of diarrhœa, which lasted for some weeks, glycosuria recurred, and the sugar in the urine amounted to 1·4 per cent. The motions were yellow and of evil odour. Under treatment with milk diet and peptone, castor oil, and tanalbin as an astringent, the stools improved in character and became less frequent, and ultimately natural. The sugar also diminished and disappeared in about a fortnight. Soon afterwards the patient could take any desired quantity of starch with impunity, but 30 grammes of glucose still induced glycosuria.

One would naturally look for the cause of the glycosuria in such cases in the extension of an infection to the pancreas, but it must be admitted that the outcome of the pancreatic efficiency tests has hitherto lent no countenance to such a view. Reicherz connects this variety of persistent glycosuria with that observed by Pflüger after removal of the duodenum of a frog, the pancreas being carefully guarded from injury. A like result followed mere division of the nerve connexions between the duodenum and the pancreas.

Emil Zak[34] has described two cases of corrosive poisoning, one by alkali and the other by mineral acid, in which glycosuria occurred. Although the first patient survived for ten days, the glycosuria lasted only two days. In these cases the corrosion was so extensive that one fails to see why the injury to the duodenum should be held specially responsible for its causation, as Zak suggested that it was; and Eichler and Silbergleit[35] who, in consequence of Zak's observations, made experiments upon dogs, found that severe corrosion, or scorching, of the duodenum excited glycosuria in these animals, but that the same result followed when other portions of the intestine were similarly treated. They regard the glycosuria as due to emptying of the glycogen reservoirs, as after other violent insults to the organism.

Clearly it behoves us to observe carefully the condition of the intestinal functions in cases of diabetes, and to treat any intestinal disorder which may be present. It is not unlikely that evidence of enteritis will be found in more cases than might be supposed, and I may recall the fact that in the case under my own observation which ended in recovery, described earlier in this lecture, there had been looseness of the bowels for some time before the onset of the jaundice and detection of the glycosuria.

The great importance of the observations quoted lies in the fact that they afford evidence that in some cases of diabetes the metabolic disturbance depends upon primary morbid conditions which are amenable to treatment, and raise the hope that further investigation may reveal other groups of cases in which recovery is possible.

Glycosuria with Febrile Disorders.

Spontaneous excretion of sugar in association with febrile diseases by patients who are not the subjects of diabetes is certainly a rare phenomenon, but there is good reason to believe that when it occurs it is a manifestation of a lowering of tolerance for carbohydrates which is much more common. I have already referred to this subject when speaking of potential glycosuria, and to J. Strauss's observation that such lowering of tolerance is not limited to glucose, but extends to starch also. Von Noorden[36] states further that in pneumonia a noteworthy hyperglycæmia may be present, although no sugar appears in the urine. It seems probable that implication of the pancreas is responsible for the alimentary and spontaneous glycosuria in fevers.

Although I have made, and have had made, many examinations of the urine of patients with lobar and bronchopneumonia, I have not met with any example of glycosuria in those diseases, but, as an example, a case recorded by an Italian physician, Gazzetti,[37] may be referred to. The patient was a man, aged 45, who had not exhibited any symptoms of diabetes previously, who during an attack of pneumococcal pneumonia excreted traces of sugar on the second day. The day's output of glucose rose to 7 grammes on the eighth day, and to 12·4 grammes on the twelfth day, and thereafter diminished day by day, and by the sixteenth day had wholly disappeared. The temperature fell by crisis on the ninth day. Some time later tests with glucose and lævulose demonstrated a complete recovery of tolerance. It is not stated that tests of pancreatic efficiency were applied.

Similar temporary glycosuria has been observed in other specific fevers, such as scarlet fever and variola, and also in malarial diseases. Becker[38] has recently called attention to its occurrence in phlegmonous diseases. He quotes briefly 19 cases, from amongst a total of 8000 cases of abscesses, carbuncles, and the like, in which temporary glycosuria was observed, in all of which the excretion of sugar ceased on recovery. In 10 cases complete recovery of tolerance was demonstrated by the administration of 100 gramme doses of glucose after intervals which varied from 1 to 11 years after recovery. There is no obvious connexion, of course, between such occurrences and the special liability of diabetic patients to phlegmonous lesions.

In connexion with fevers will be noticed the same peculiarity which is so frequently encountered in the occurrence of glycosuria—namely, that excretion of sugar is rather the exception than the rule when one of its recognised causes is at work—a peculiarity which appears to stamp it as, in most instances, a secondary, rather than a primary symptom.

In my third, and last lecture, I propose to discuss that which is perhaps the most interesting part of my subject—namely, the association of glycosuria with disorders of the ductless glands.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—An ordinary meeting of this society will be held at the West London Hospital to-day (Friday, March 1st) at 8.30 P.M., when Mr. F. L. Provis will read a paper, Pain in Women in the Iliac Region and in its Immediate Neighbourhood. Clinical cases will be shown from 8 to 8.30 P.M.

THE SIGNIFICANCE OF THE SYMPTOMS IN CASES OF DUODENAL ULCER.[1]

BY C. MANSELL MOULLIN, M.D. OXON., F.R.C.S. ENG.,

CONSULTING SURGEON TO THE LONDON HOSPITAL; VICE-PRESIDENT, ROYAL COLLEGE OF SURGEONS OF ENGLAND.

I DO not think the subject I have chosen needs an apology. For some years past ulceration of the stomach and duodenum has occupied the attention of surgeons more and more, and as a consequence our views with regard to it have undergone a material change. The findings of post-mortem pathology have had to be corrected in the light of what has been seen in the living, and though many of these corrections have been of a very extensive description, I believe, and I hope I shall be able to prove to you that the limits have not yet been reached.

Symptoms of Duodenal Ulcer.

Ten years ago duodenal ulcer was regarded as a pathological curiosity, very rare and hardly to be diagnosed during life. In 66 years at Guy's Hospital there were only 70 cases in which a duodenal ulcer was found post mortem. In the last ten years, since Moynihan's first paper upon the subject, chiefly owing to his work and to that of the brothers Mayo in Rochester, it has been found to be so common that there is scarcely a surgeon who has not operated upon one or more cases, and not a few who can count their operations by the score. The symptoms are too well known to make it necessary for me to enumerate them. The patient is usually of middle age. Duodenal ulcer does not appear to be a complaint of young adult life in the way that gastric ulcer is—and men seem to be more liable to it than women. For months the patient has complained of a sensation of fulness and distension after meals. At first it was only discomfort. Then it became actual pain, especially after the chief meal of the day. Soon it occurred after every meal, beginning earlier, if the food was liquid, but not for some hours in the case of a heavy meal. One peculiar feature is that it is especially severe at night, and another, perhaps even more striking, is that relief can nearly always be obtained at once by taking food, so that the patient gets into the habit of carrying biscuits about with him or taking them to bed with him at night. This pain is felt nearly always at the same spot, just to the right of the epigastrium, and is relieved by pressure. Heartburn is common, but actual vomiting is rare, unless stenosis has already set in. Hæmatemesis seldom occurs, and when it does is very grave. Melæna is quite common, but is often overlooked, as the amount in most cases is small. Locally there is nothing to be felt but a certain amount of tension of the upper segment of the right rectus. These symptoms may continue for months and then pass away completely, so that for a time the patient is perfectly well. Worry, exposure to cold, ill-health of any kind, will bring them all back again even after many years. Recurrence with intervals of complete freedom is very characteristic.

Taken together, these symptoms make up a picture with which we are all familiar. The disorder is not a functional one. I confess that I have all a surgeon's scepticism with regard to functional disorders. I do not think it right to call a disorder a functional one because we do not happen to know the organic lesion that causes it. It is not consistent with scientific work to assume that a thing does not exist because it has not yet been seen. But I do not think that anyone now would question that there is a definite organic change of some kind present in all these cases. Certainly every one will agree that the proportion of instances in which such an organic change is found is rapidly increasing, and is far higher than it was a few years ago. And the part of the digestive tract in fault is almost certainly the duodenum, though it does not follow that the mischief is confined to this. But the point about which I am in doubt, and the point which I wish to raise to-day, is, whether there is always an ulcer in these cases, or the scar left by an ulcer; and still further, whether when there is or has been a duodenal ulcer, this ulcer is really the cause of the symptoms. I admit that when there is one it makes them worse, but is it the cause? Is it not possible that it may only be a complication, aggravating everything else? I personally do not think it by any means proved that it is the cause, and for my own part I am convinced that another explanation can be found which fits the facts far better.

In many instances, of course, it is obvious at the first glance that there really is an ulcer. There can be no question about it. There is a reddened area on the peritoneal surface of the duodenum, visible as soon as the abdomen is opened, raised and thickened, a sure sign of ulceration beneath. But this is not so in all. In a good many all that is ever found is a white patch on the serous coat, which may or may not be adherent to the structures beneath, and which may or may not separate from them when pinched up between the finger and thumb. Is this a scar marking the site of an ulcer that has healed? and if it is an ulcer that has healed why should a scar—a simple scar that certainly cannot cause stenosis or obstruction—give rise to the peculiar characteristic pain and all the other symptoms that are present in these cases? In others, again, even this is wanting. In one, for example, recorded as operated upon by Moynihan, the case of a man, 26 years of age, who had been ill for nine months and who had had hunger pain practically the whole time, not even this could be found at the operation. There was nothing abnormal to be seen when the abdomen was opened. And this case does not stand alone. I could mention others.

In several of my own cases I have been so much struck by the discrepancy between the symptoms (which, be it known, were relieved by operation) and the only lesion I could find, one that I can only describe as a white patch upon the peritoneal coat, that I asked Dr. H. M. Turnbull, the director of the Pathological Institute at the London Hospital, if he could give me any information upon the subject. Dr. Turnbull's reply more than confirmed my suspicions. He told me that he had found comparatively deep ulceration upon the mucous surface of the duodenum without any evidence on the serous surface to show what was going on beneath (this, of course, was post mortem; there would have been some reddening during life); and conversely a puckered, scarred condition of the serous coat without anything in the interior to correspond. In one instance, he wrote to me "the serous coat showed a marked thickening with small nodules and adhesions, so much so that I pointed it out to the students as an indication of a malignant ulcer inside. On opening the pylorus there was no abnormality."

In short, it seems to me that it cannot be denied that there may be an ulcer in the duodenum without symptoms of any kind (in many instances in which an ulcer has been found post mortem its existence had never been suspected during life); that the characteristic symptoms may be present without even so much as a white patch on the serous coat; that fairly deep ulceration may occur in the mucous membrane without visible change on the serous surface, post mortem at any rate; that a great deal may happen upon the serous surface in the way of thickening and adhesion without anything to correspond beneath; and that the presence of a trivial scar, far too small and too superficial to cause stenosis or obstruction, is not enough to account for the symptoms assigned to duodenal ulcer; and still less for their recurrence after perhaps years of freedom.

It is much too readily taken for granted that the symptoms of which I am speaking are evidence of ulceration. Ulceration, when it is present, intensifies them and prevents their getting well, and probably is always present in cases that obstinately persist, or return again and again at short intervals; but ulceration is not an essential factor. They may occur in the most typical form without anything of the kind. It is an addition and an accident, due in general to some slight injury causing extravasation and occurring, therefore, chiefly in those parts of the bowel that are softest, thickest, and most vascular. There are, however, two symptoms which must be excluded from this—profuse hæmorrhage and perforation. When these occur ulceration is always present, but they really are complications of duodenal ulcer rather than symptoms, and fortunately only occur in a small proportion.

Pain.

As I shall only be able to deal with two or three of these symptoms, I propose to begin with pain, which from the striking features it presents, the time that elapses after a meal before it comes on, and the way in which it is relieved by food, is often spoken of as the most characteristic of all, and alone, by itself as sufficient to justify the diagnosis of

[1] A paper read before the Cardiff Medical Society on Feb. 23rd, 1912.

duodenal ulcer. This emphatically must be disallowed at once. Hunger pain, as it is called, may and does occur in its most typical form in many other disorders besides duodenal ulcer. I have known it present when the only discoverable lesion was a chronic ulcer on the lesser curvature of the stomach at the cardiac end, quite close to the œsophagus. Others have described it in connexion with gallstones, chronic inflammation of the appendix, and other abdominal troubles. And what is more significant still, in more than one instance in which an operation has been performed because of hunger pain, no lesion of any kind has been discovered, though the patient has been cured of his symptoms. The relation, therefore, of hunger pain to duodenal ulcer is clearly not so obvious and conclusive as some would have us believe.

The immediate cause of the pain is a matter of considerable interest in connexion with this. The usual explanation for it is that it is due to the acid gastric juice coming into contact with the raw surface of the ulcer; and the lateness of its occurrence in duodenal as compared with gastric ulcer is explained on the supposition that the acid contents of the stomach do not pass through the pylorus until some hours after the food has entered the stomach. Some authors indeed have been so ingenious as to be able to diagnose the position of an ulcer in the stomach by the time at which the pain began. I do not know if they do so still, but I expect they do, for if a positive statement, right or wrong, once gets printed in a book it apparently becomes immortal. As an effort of the imagination these suggestions are decidedly not without merit, but that is the best that can be said of them. There is not the slightest foundation for them. They are pure assumption. In the quietest possible way they presuppose the existence of an ulcer. They do not prove it, or attempt to prove it. And then, not satisfied with this, they presuppose that if there is an ulcer the effect of acid upon it would be the same as the effect of acid upon a sore place on the hand. As a matter of fact, ulcers of the stomach or duodenum may exist for months exposed to acid all the time without the patient suffering any inconvenience; and patients with proved (not supposed) gastric ulcer may swallow acid of far greater strength than is ever secreted in the stomach without experiencing so much as an unpleasant sensation. Lennander, too, has shown, and it has been confirmed by surgeons times without number, that the walls of the stomach and intestine, whether there is an ulcer or not, are entirely devoid of sensibility to stimuli of this kind. They may be cut with scissors or cauterised, or burnt with strong acids without the patient being so much as aware that anything is being done. All this, therefore, about the effect of acid causing pain in this way is manifestly pure imagination.

It is often said in opposition to this that all the same there must be something in it because alkalies relieve pain, and alkalies neutralise acids. I have no quarrel with the facts. Alkalies neutralise acids. They also relieve pain. So do food, and carminatives, and even alcohol, when judiciously taken, but none of these neutralise acids. And there is another difficulty—in the rapidity with which relief follows. It is impossible to think that in the case of a duodenal ulcer the dose of soda has had time to pass through a stomach half-filled with semi-digested food and neutralise the contents of the duodenum beyond. No; there is no help to be got from alkalies—no help for the theory, at any rate, however useful they may be in practice; and the idea that pain is due to the direct action of the acid gastric juice upon an ulcerated surface, and that there must be an ulcer because there is pain, must be altogether given up.

As a matter of fact, the real explanation for this pain is quite different. The immediate cause, until, that is to say, the stage is reached when the peritoneum becomes involved and another factor is introduced, is nothing more nor less than muscular cramp, violent spasmodic contraction of the unstriped muscular fibre at and near the pylorus. If the contraction is comparatively moderate, so as merely to cause a certain degree of tension, there is only the sensation of fulness. When it is more severe the sensation becomes pain, which is described as bursting—a phrase, it may be noted, patients are very fond of using. It describes literally what they feel. In the worst cases this pain becomes almost unbearable, and leaves behind it when it subsides a feeling of soreness and tenderness that may last for days. If there is any mechanical obstruction the contraction comes on in waves, one succeeding another in regular sequence; but if the passage is free, except for spasm, and the stimulus is continuous, the contraction is maintained without intermission, until at last it gives way either because the muscular fibres are tired out or the nerve centre is exhausted.

The immediate stimulus that starts this contraction is probably always the food as it leaves the stomach. At the beginning of digestion, as is well known, muscular action is comparatively slight. Later it increases in vigour as the stomach becomes empty, perhaps caused in some measure by the increased acidity of the contents. So long as the mucous membrane is normal and healthy, and there is no obstruction, spasmodic or mechanical, the contraction is not felt. It is absolutely imperceptible. But if from any cause the responsiveness of the mucous membrane to stimuli becomes abnormally raised, at once irregular spasmodic contraction sets in, in place of muscular action in orderly sequence, and with it, as its inevitable attendant, pain. There may be an ulcer or there may not. The presence of an ulcer is certainly not necessary. Muscular spasm may occur in its worst and most painful form without anything of the kind. All that the pain really indicates is that there is an irritable, hyper-responsive condition of the mucous membrane, so that a stimulus which in ordinary circumstances would produce only a normal result calls into play a reaction which is not only excessive in amount, but which persists and continues so long as this condition is present. If this goes on, if the spasm and contraction are kept up, it ends in the establishment of a typical vicious circle, the increased responsiveness of the mucous membrane intensifying the muscular spasm and the increased muscular spasm irritating the mucous membrane still more by crushing the tender surfaces together. It is the formation of this vicious circle that holds the secret not only of the symptoms that are present in what is commonly known as duodenal ulcer, but of the reason why they are relieved with such certainty and success by the operation of gastro-enterostomy when all else has failed.

Nor does this rest upon mere conjecture. The occurrence of this muscular spasm has been actually seen and watched, not only in cases in which there is pyloric stenosis, in which, of course, it is well known, but also in those in which there is no obstruction nor ever has been. There are many cases recorded now in which the abdomen has been opened under local anæsthesia and the contraction of the muscle about the pylorus has been watched from start to finish, the muscle slowly swelling up and becoming hard under the influence of some distant stimulus, and the patient simultaneously complaining of the characteristic pain. That this is the true cause of the pain, and not the irritation of the surface of an ulcer by the acid gastric juice, may be regarded as certain, and it is no less certain that the pain may occur, and occur with the greatest severity, in cases in which there is no ulcer, and in which there never has been one.

The late onset of the pain when the duodenum is involved, as compared with its early beginning in the case of the stomach, presents no difficulty. It is simply due to the fact that the vicious circle is not started so soon. A certain vigour of contraction is required for it, and it is well known that the movements of the stomach increase in intensity as it becomes empty. It is not due, as is so often stated, to the lateness with which food enters the duodenum. This is simply another product of the imagination. Barclay and Hertz[2] have both of them shown as a result of X ray work that bismuth, at any rate, and therefore presumably the food that is mixed with it, begins to pass through the pylorus almost at once, long before the pain commences. And the relief experienced when food is taken, which has gained for this pain the name of hunger pain, is simply due to the fact that food entering the stomach engages for the moment the whole attention of the local nerve centres, and so cuts the vicious circle across for the time being. Unfortunately, the effect does not last long. Something more is required if the circle is to be permanently broken.

Hæmorrhage.

The second symptom, or supposed symptom, of duodenal ulcer to which I wish to call your attention is hæmorrhage. It is of very frequent occurrence, much more frequent than is usually believed, but unless it is profuse it is no proof of the presence of an ulcer and cannot be accepted as evidence that there is one. Profuse hæmorrhage coming from the

[2] THE LANCET, May 6th, 1911, p. 1189.

duodenum, which fortunately is of rare occurrence, is another matter. This is probably always due to an ulcer that has eaten its way into the wall of an artery, and demands immediate operation. But what are commonly called occult hæmorrhages, small quantities of blood occurring in the fæces, so small that they can only be detected by chemical analysis, the hæmorrhages that are usually met with in cases of this kind, do not mean anything of the sort. All that they mean is that there is great congestion of the mucous membrane, so that the blood pours out from the capillaries that have given way and escapes between the epithelial cells. They do not mean that there is any such thing as an ulcer, or even a breach of the surface visible to the naked eye. I admit this is difficult to prove of the duodenum, for the duodenum is seldom opened and inspected during life; but it is so certain in the case of the stomach that it can hardly be doubted as equally true of that portion of the duodenum which, geneticallv and anatomically, is so much more closely related to the stomach than it is to the rest of the intestine. This is the condition which Hale White described in connexion with the stomach as gastrostaxis.[3] There is no ulcer. The surface of the mucous membrane is unbroken, but the blood pours from it. I have on three occasions opened the stomach for hæmatemesis expecting to find a gastric ulcer, as all the classic signs of gastric ulcer were present, without being able to find one. I admit that in such circumstances an ulcer may easily be overlooked. During life such an ulcer often appears as a fine linear fissure, out of which the blood trickles slowly in a continuous stream, and I have myself pointed out how easy it is to overlook a minute opening in the wall of an arteriole; but the blood in these cases did not come from any single spot but from a surface which was to all appearance unbroken, and there are at least four cases on record in which an operation of this kind having terminated fatally, the most minute and searching examination post mortem failed to reveal the presence of any ulcer.

Moreover, it is well known that severe and even fatal hæmorrhage may take place from the stomach and intestine after abdominal operations, without any evidence of ulceration being found post mortem. I have known this occur after such a simple operation as ligature and removal of a small portion of omentum. There can, therefore, be no doubt that hæmorrhage may, and often does, take place from the stomach without any such thing as ulceration, and if this is true of the stomach it is almost certainly equally true of the duodenum. Melæna, in short, where all the other symptoms point to the presence of an ulcer in the duodenum, may be regarded as confirmatory evidence; if it is in large amount, as strong confirmary evidence; but there can be no question that ulceration of the duodenum may and does occur without melæna, and that conversely small hæmorrhages from the duodenum are equally common without ulcer.

Hyperchlorhydria.

The third symptom which I should like to discuss because of the frequency of its presence in cases of supposed ulcer of the duodenum is what is known as hyperchlorhydria. I am not quite sure that I understand all that is implied by this word, or that physicians who make use of the word are agreed among themselves as to its exact significance. Etymologically I have no doubt, from the high authorities that use it, it is quite correct, and there is no doubt that any layman who is told that he is suffering from a complaint with such a name must be duly impressed thereby. But I cannot free myself from the uneasy suspicion that this is one of those long and impressive words that are coined from time to time, if not for the actual purpose of concealing what we do not know, at any rate possessing that effect. It does not matter so very much, perhaps, if it only hides our ignorance from our patients. The days of the early Victorian physician have not gone by yet, and faith, or what we term suggestion, still plays a great part in treatment. But it does matter a very great deal if it conceals our ignorance from ourselves, and of that I am afraid there is some danger.

The general view appears to be that hyperchlorhydria implies nothing more than a morbid excess of free hydrochloric acid in the contents of the stomach. Employed in this sense the word is harmless, but inasmuch as an excess of this kind may be produced in more ways than one, and may mean many different things, it must be clearly understood that the word merely connotes the symptom and not the cause, whatever it may be, that underlies that symptom. In one respect I admit hyperchlorhydria is more closely associated with duodenal ulcer than either hunger-pain or hæmorrhage, for an excess of hydrochloric acid undoubtedly assists the process of ulceration. Ulcers occur chiefly—in fact, almost entirely—in those portions of the stomach and duodenum that come most closely into contact with acid, and when the acid is in excess the digestion and disappearance of any portion of mucous membrane the vitality of which has been already lowered by thrombosis or bruising naturally take place more easily. But though hyperchlorhydria is present in about 60 per cent. of cases diagnosed as duodenal ulcer, and though when present it may help in the actual production of the ulcer, its presence even in an exaggerated form is not evidence of the existence of an ulcer.

The simplest explanation for the presence of an excess of free hydrochloric acid in the stomach is that there is an excessive amount secreted. For some reason or other that portion of the mucous membrane which is concerned with the secretion of acid has been rendered unduly responsive to the stimuli it receives. Just as the increased responsiveness of the mucous membrane of the duodenum leads to pyloric spasm and hunger-pain, so that of the mucous membrane of the acid-secreting portion of the stomach leads to hyperchlorhydria. It is not surprising, therefore, that these two should occur together with such frequency, but neither the one nor the other is proof of the presence of an ulcer. There may be an ulcer or there may not. If there is one it usually makes all the symptoms worse; but when it does occur it is an addition and more or less an accident.

Causation.

But what, then, is the real significance of these symptoms? What is the condition of the stomach and duodenum that underlies them all? And why do hunger-pain, pyloric spasm, occult hæmorrhages, gastrostaxis, and hyperchlorhydria occur in this association? For myself, I am convinced that the solution is to be found in the intensely hyperæmic and hyperæsthetic state of the mucous membrane present in these cases. This, to my mind, is quite sufficient to account for the whole. The mucous and submucous layers of the bowel are swollen and thickened. All the interstices in the adenoid tissue that is so abundant are choked with lymph. The lymphatic follicles themselves are so much enlarged that they project above the surface, where they are in constant danger of breaking down. The blood-vessels are distended to such a degree that the slightest pressure is sufficient to make them give way, and if the extravasation is near the surface and there is an excess of free hydrochloric acid ulceration is almost certain to follow. Of all this there can be no doubt, and it is enough, and more than enough, to account for the symptoms; but because almost the whole of this disappears with the life of the patient, little or no attention has hitherto been paid to it. After death, when the blood pressure has fallen to zero, there is little or nothing to be seen but the staining of old and recent extravasations and a few enlarged follicles. This is enough if the signs are read aright—they tell the tale quite clearly of what has been going on; but if an ulcer happens to have formed, though it may be quite late in the day and though it may have healed already, it stands out as such a prominent feature that it gets the blame for the whole. The primary cause is overlooked.

This rests mainly upon clinical evidence it is true. In operating in cases of duodenal ulcer the duodenum is seldom opened sufficiently for the interior to be inspected. But it is thoroughly borne out by what has been seen times without number in the case of the stomach. It is curious how the old observations made of the interior of the stomach of Alexis St. Martin appear to have become forgotten, obliterated, I suppose, by more complicated methods of inquiry. Very few, I imagine, except operating surgeons, ever have the chance nowadays of seeing the mucous membrane of the stomach during life and noting the extraordinary difference in its appearance from that which it presents after death. On the post-mortem table the mucous membrane of the stomach is a thin, pale grey structure that falls into irregular folds and wrinkles according to the way in which it is handled. During life, when it is full of circulating blood and lymph, it is soft and thick. It keeps its own shape and its colour is a brilliant red. During active digestion, when the amount of blood circulating through it is very much larger, the difference is greater still. And when, from some pathological

[3] THE LANCET, Nov. 3rd, 1906, p. 1189.

cause, the hyperæmia is so intense that the surface actually weeps blood, all resemblance disappears. It is difficult to realise that the two structures are the same. This is the condition that precedes ulceration and gives rise to the symptoms for which the ulcer, when there is one, always gets the blame, and which apparently are so inexplicable when no ulcer, or only a trivial scar, can be found.

Hyperæmia such as this may be caused in many different ways. Exposure to cold is one of the most common. It is notorious how prone this is to bring back all the symptoms of duodenal ulcer, even after many years of absolute freedom, not, as is usually stated, because the ulcer has been lying latent all that time and suddenly springs into life again, but because exposure to cold is one of the most frequent causes of internal congestion, and in any given individual nearly always affects the same part of the body time after time, so that if the duodenum was involved once it will become involved again. Jaundice, it is well known, may be caused in this way if the congestion involves that part of the duodenum into which the bile-duct opens. If the congestion is only slight the symptoms soon disappear, and it is said to have been an attack of acid dyspepsia, which has been cured by alkalies or by starvation. If it is more severe and the mucous membrane becomes over-responsive and irritable, so that the passage of food excites an attack of muscular spasm, a vicious circle is set up; the symptoms persist and grow more and more severe, and the patient is said to be suffering from duodenal ulcer.

Septic poisoning, such, for example, as that which occurs in so many cases of chronic appendicitis and gall-stones leading to persistent ill-health without anything definitely wrong, is, I believe, still more common as a cause. The influence that septic poisons exert upon the mucous membrane of the stomach and first part of the duodenum seems to me to be scarcely sufficiently appreciated. The gastric ulcer of young women, in whom there is often no ulcer at all, but merely hyperchlorhydria and gastrostaxis, is notoriously due in a very large proportion of cases to the persistent swallowing of septic poisons from the mouth. I have cured many such by sending them to the dentist. In these the septic poison exerts its action directly on the mucous membrane of the stomach. It does not pass the pylorus. But it is no less efficacious when it is brought through the blood stream, and then it affects stomach and duodenum indiscriminately. Hæmorrhage into the stomach, the result of intense congestion leading to coffee-ground vomiting, is among the commonest incidents of the later stages of all forms of acute septic poisoning. Real duodenal ulcers, it is well known, are not infrequent complications of septic burns, and there can be very little doubt that for every case in which an ulcer occurs there are many more in which the congestion and swelling of the mucous membrane of the duodenum go no farther. And now that attention has been called to it there are many cases on record in which violent hæmatemesis has occurred after operations in septic cases of appendicitis and other similar troubles Septic poison, in short, either brought into contact with the mucous membrane of the stomach, or carried by the circulation into its vessels, will cause intense congestion, hypersecretion, hæmorrhages, and even ulceration. When the poison is generated in the mouth and is swallowed, the stomach chiefly is involved, and gastrostaxis, hyperchlorhydria, and ulceration follow. Possibly the excess of acid may neutralise the poison more or less and prevent its extending farther, and this may even be protective on the part of the stomach. When it is brought by the blood stream the duodenum is often affected as much as the stomach, sometimes a great deal more, and hyperæmia with intense irritability, pyloric spasm, and hunger-pain result. In the worst cases, those especially in which the stomach is affected as well, so that there is a great excess of free acid, ulceration is very likely to occur too, but the ulcer is the consequence, not the cause. It is an addition, which aggravates all the symptoms and makes them more persistent, but it is not the primary agent.

Exposure to cold and septic poisoning, however, by no means exhaust the list of possible causes. In some people this part of the digestive tract is so sensitive that even trivial injuries lead to a serious degree of congestion with its consequences. Not so long since I was consulted by a young man for a trivial attack of traumatic synovitis of the knee. He seemed to me to attach an undue amount of importance to a simple sprain; but when I asked him about it, he said at once: "You do not know why; I shall get jaundice; I always do if I hurt myself like this." And it was quite true; he did.

As a matter of fact, we know as yet very little of the mechanism that controls the vascular and nervous supply of the pyloric region of the stomach and duodenum. It is evidently extraordinarily complex and delicate, and liable to be upset in many different ways. And we know still less of the extent of the powers which these parts of the body possess of excreting poisons from the blood though they must be very considerable. But that the symptoms which are usually grouped together as indicative of duodenal ulcer do not prove in any way the presence of an ulcer, but are accounted for equally well by attacks of congestion and hyperæmia, and the establishment of a vicious circle, started by something that irritates the exceedingly sensitive surface of the mucous membrane, seems to me not to admit of doubt. If the symptoms are recent and slight, drugs and diet effect a cure, and the case is said to have been one of acid dyspepsia or hyperchlorhydria, because after some kind of test meal an excess of free hydrochloric acid is sometimes, but by no means always, found. In cases that have lasted longer, in which a vicious circle, such as I have described, has already been established, the same good result may follow; but as a rule much longer treatment, combined with rest in bed, is required, and after all the symptoms have disappeared recurrence is very likely to take place on the most trivial provocation, such as exposure to cold. In the worst the only means of breaking the circle is an operation—gastro-enterostomy—and that fortunately is safe, effectual, and final. There is no recurrence after gastro-enterostomy. Whether there really is ulceration or not in such a case is perfectly immaterial. So far as treatment is concerned it does not enter into the question. Operation, of course, is compulsory if there is serious hæmorrhage, for this in the case of a duodenal ulcer rarely occurs unless an artery has been eroded, or if the severity of the local symptoms causes even a suspicion that perforation may possibly occur. But it is no less necessary in cases in which, from the persistence or obstinate recurrence of the symptoms in spite of medical treatment, it is evident that something more thorough is required. In many of these cases there may be one or more ulcers, and in many more there are white patches on the serous coat of the duodenum which possibly may be the scars of old ulcers; but the symptoms are not due to the ulcers, though they may be made worse by them, and they are certainly not caused by the white patches, whether they are scars or whether they are not.

Wimpole-street, W.

THE DIFFERENTIAL DIAGNOSIS OF CERTAIN INFECTIOUS DISEASES.[1]

BY FREDERIC THOMSON, M.B., C.M. ABERD., D.P.H.,
MEDICAL SUPERINTENDENT, NORTH EASTERN FEVER HOSPITAL.

I FELT much honoured when I was asked to open a discussion at the Æsculapian Society, and as your President suggested to me that some remarks on the differential diagnosis of infectious diseases might be acceptable I decided to take his kindly advice. In the time at my disposal I can only do this in a limited way, and, accordingly, I will only attempt to discuss the diagnosis between a few of them.

Without doubt, it will interest you to know what certain of the error rates approximately are. For the purpose of showing this in scarlet fever and diphtheria I have taken the admissions to my hospital for the years 1906 to 1910 inclusive. In rough figures during these five years 13,000 patients were admitted certified to be suffering from scarlet fever, and of these, in my opinion, 8 per cent. were not so suffering. During the same period about 3000 cases certified to be suffering from diphtheria were admitted, and of these 22 per cent. were suffering, not from diphtheria, but from other diseases. I must, of course, admit that these percentages cannot be accurate because I myself make wrong diagnoses, and the frequency with which I do so I cannot estimate in the least.

In the year 1902, when small-pox was epidemic in London, some 8000 patients were admitted into the institutions of the Metropolitan Asylums Board so certified, and of

[1] A paper read before the Æsculapian Society on Feb. 2nd, 1912.

these 7·7 per cent. were mis-diagnoses. In the year 1903, when the epidemic was over, roughly 400 cases were admitted certified to be suffering from small-pox, and of these 18·2 per cent. were not so suffering. Of the 7·7 per cent. error-rate of 1902, 2·5 was due to mistaking chicken-pox for small-pox, while of the 18·2 error-rate of 1903 8·7 was due to the same cause.

When one considers the difficulties with which the practitioner is beset, such as indifferent light, uncleanly skin, the anxiety for several reasons to come to a definite diagnosis, and so on, should one consider these error-rates high or low? When I consider the high proportion of mild and ill-marked attacks of scarlet fever in recent years I must regard the percentage error as low. I do not think the diphtheria error-rate can be called low, and I imagine it is partly accounted for by the natural desire of the physician to send the sufferer to hospital in order that there may be as little delay as possible in the administration of antitoxin.

I must say, however, that I think the small-pox error higher than it should be in non-epidemic times; and chicken-pox should not be mistaken for small-pox to anything approaching the error-rate. I have often been told and often heard it said that medical men so seldom if at all get the opportunity of seeing small-pox. I have seen many a case of typical chicken-pox mistaken for small-pox, and I have been driven to the conclusion that this is not so much due to want of experience of small-pox as to the neglect of the study of chicken-pox. It is well known that great difficulty may occur in distinguishing between these two diseases, but the difficulty is rare and the error common. Some may think I strain this point, but I wish to emphasise the fact that though the medical man may have little chance of studying small-pox clinically, yet he will go a long way to minimise that difficulty if he studies chicken-pox closely.

Before I come to the diagnosis between the few diseases I purpose attempting to-night I wish to say that in no class of disease is careful and thorough examination more necessary than in the infectious diseases. It is essential to examine the whole skin surface, and the mouth and throat must be examined minutely in as good a light as possible.

Scarlet Fever and German Measles.

If the attack of either scarlet fever or German measles is well marked it is well-nigh impossible to mistake the one for the other if the observer is fairly well acquainted with each disease. Often, however, the attack is ill-marked, and to distinguish between an ill-marked attack of scarlet fever and a case of German measles which mimics the rash of that disease requires minute examination, a sound knowledge of both diseases and a high colour sense. Even then errors will occur with our present limited knowledge.

The onset of scarlet fever is often sudden and the sufferer feels really ill. The onset in German measles is seldom sudden; the sufferer usually has but little malaise, and the eruption is often the first evidence of the disease. The manner of onset seldom helps one when distinguishing between doubtful examples of these two diseases, for in many mild attacks of scarlet fever the onset is ill-marked and the rash may be the first evidence. On the other hand, though it is not common, the individual who is the subject of an attack of German measles may, comparatively suddenly, feel really ill, and I think this is rather more common when the adult is attacked by this disease.

I cannot say that I place much reliance upon the enlargement of certain glands in German measles from a diagnostic point of view, but it will be in favour of German measles if the post-auricular and occipital glands are much enlarged provided the head is not verminous. It is common for these glands to be enlarged, at all events amongst the poorer classes, from that cause. I may say that well over 90 per cent. of the female patients admitted to my hospital have either pediculi capitis and nits or nits alone. The percentage in the male sex is, of course, much less. Stiffness of the back of the neck and marked enlargement of the cervical glands for a day or two before the rash comes out are somewhat in favour of German measles.

Vomiting or pronounced nausea is frequent before the advent of the scarlet fever rash in children, and even in mild attacks is comparatively common, whereas in German measles it is rare. Of course, incidental vomiting may occur before the appearance of the German measles rash due to such common causes as errors in diet, hot weather, &c., and no doubt the disease may increase the chance. Nevertheless, the fact remains that vomiting in the invasion stage is highly in favour of scarlet fever, but it is to be remembered that vomiting or pronounced nausea is much less common when an adult is attacked.

Evidence of catarrh may help one in the invasion stage and for a day or so after the rash comes out, but only, I think, in so far as the ocular conjunctivæ are concerned. In a sharp attack of scarlet fever the ocular conjunctivæ may be considerably injected, but we are not concerned with well-marked attacks. In mild cases of scarlet fever the ocular conjunctivæ are rarely much injected, and are, indeed, commonly quite clear, whereas the condition is quite usual in German measles. On the other hand, it must not be forgotten that the ocular conjunctivæ may be quite free from injection in German measles, and even in quite mild attacks of scarlet fever some injection is occasionally seen.

The condition of the fauces is sometimes a help when one is in difficulty, but I must admit it is seldom so. The injection in German measles is diffuse, while in scarlet fever it is usually more pronounced on the uvula and along the free edge of the soft palate than on its surface. In many cases, however, this is of no help, and, in fact, in a good many very mild attacks of scarlet fever little, and in some no, injection is to be seen.

It may be easy to distinguish between the rashes of scarlet fever and German measles or it may be difficult or even impossible. If the rash of German measles is seen when it first comes out it is almost always quite easy to diagnose the case, for the light pink macules cannot well be mistaken for the rash of scarlet fever. However, in a few hours after the advent of the German measles rash it may, and does with considerable frequency, lose its original character and becomes diffuse. When this change takes place the rash may be more or less like scarlet fever; in some cases it is still comparatively easy to distinguish, in some difficult, and in others quite impossible. In a proportion of these cases, I think in a considerable majority, the macules and papules comprising the rash are not so well defined as in the rash of scarlet fever; in some they are exceedingly ill-defined. Occasionally, however, the mimicry of an ill-defined rash of scarlet fever is complete.

The colour of these rashes is a point of the first importance, and I wish I could describe this, for when these two diseases come to resemble each other the colour of the rash is often a great aid to diagnosis. The light pink of the early German measles macule is often greatly lost when the rash becomes diffuse, but, I think, almost always a tinge of pink is to be seen, and that tinge of pink is very rarely seen in scarlet fever. Here a high colour sense is necessary for the diagnostician and we have not all got that.

The distribution of these rashes is often of assistance in coming to a diagnosis. When the German measles macules first appear on the face and show in the circumoral region no error is likely to be made; but even when the German measles rash has become diffuse help is often to be found. The macular and papular rash of scarlet fever when profuse does not show the same niceties of distribution as when it is sparse or limited; but whatever the amount of the rash may be it very rarely occurs in the circumoral area or close by the side of the nose. This, however, is not of great assistance, seeing that when the rash of German measles has become diffuse it has often faded from the circumoral region, but if it has not completely done so the point is very useful. It is to be remembered that on rare occasions in German measles the rash does not affect the face at all, and that in scarlet fever a simple erythema or flush is not uncommon in the circumoral region. Further, in scarlet fever if there is a catarrhal condition of the nose some points of irritation may show in this region; this is not rare, and I have seen it cause doubt to a good diagnostician more than once. The presence or absence of the rash on the palms and soles does not help one very much, for there is often no rash on them in German measles, while a flush on the palms and soles is not uncommon in scarlet fever, and the macular rash is seen there in a small percentage of the cases. When the rash of scarlet fever is not profuse or is sparse or limited, much more rash will usually be found on the inner aspect of the thighs than on the outer, particularly at the upper part. In fact, in many cases this is so marked that a triangle of rash density having for its base a line near Poupart's ligament is graphically

shown. The same distribution applies to the arms, though usually it is not so marked as in the case of the thighs. The rash of scarlet fever is also often to be found in greater profusion on the side of the trunk than at and near the centre line of the chest and abdomen. The diffuse rash of German measles rarely imitates the distribution I have mentioned; and, indeed, the rash will usually be found in greater profusion on the outer than on the inner side of the thighs. Naturally there are exceptions to these points, and I have seen the rash of scarlet fever much more profuse on the outer than on the inner sides of the thighs; likewise I have seen the rash of German measles more plentiful on the inner sides. This distribution of the rash on the thighs is much less constant in German measles than in scarlet fever.

In some cases of scarlet fever a few tiny brick-red petechiæ are to be found intermingled at certain places with the macular and papular rash. Unfortunately for our purpose of diagnosis these petechiæ occur much more frequently in intense eruptions, but they are to be seen occasionally in sparse and limited eruptions. They may occur in most parts of the skin surface, but they particularly affect certain flexures and are most commonly to be found in the flexures of the elbow-joints, and perhaps above and below the clavicles. If these are found the diagnosis is much in favour of scarlet fever as opposed to German measles.

It must never be forgotten that though the rash of German measles may have become diffuse it may not yet have done so in its entirety, and a few light pink macules may remain in their original form. If there are any left they will usually be found on the buttocks or the back of the feet.

If the rash persists for four or five days it is strong evidence in favour of scarlet fever, for the rash of German measles rarely persists for three full days. This point, though not of much value, may occasionally be of some slight assistance.

Before leaving this subject it is well to remember that the rash of German measles sometimes appears first on the trunk and may not affect the face at all; and that the macular rash of scarlet fever does rarely occur in the circumoral area.

The condition of the tongue is often of great assistance in distinguishing between scarlet fever and German measles. The tongue in German measles is usually comparatively clean or slightly furred. In scarlet fever it often becomes rapidly covered with a thick creamy white fur, through which the bright red, elongated, and swollen papillæ show as red points, the extreme tip and edges of the tongue remaining unfurred and bright red. This condition usually persists for the first two days of the disease, and then on the third day the fur commences to peel off, starting near the tip and edges, though exceptionally the peeling starts at the centre of the dorsum. In the course of 24 to 36 hours, sometimes longer, the fur has completely separated from the dorsum, except perhaps towards the base. The tongue is then quite devoid of fur, except, as I have already stated, there may be some remaining towards the base, bright red, and dotted thickly over with protruding fungiform papillæ of a similar colour. From the point of view of diagnosis the most important of these stages is the second—the peeling tongue; the first—thickly furred stage—and the third—clean stage—also have their importance, but not to the same degree. Any of these conditions common to the scarlet fever tongue may be seen in German measles, but they are uncommon, and the rarest is the peeling of the tongue. One must not forget that in many cases of scarlet fever this peculiar condition of the tongue is not seen, and the less severe the faucial affection the less likely is it to be found, but intermediate conditions between a negative tongue and the scarlet fever tongue occur with comparative frequency and may be of assistance.

The pulse-rate in German measles usually corresponds to the temperature height, but in scarlet fever for at least the first two days of the disease it is much more rapid than is to be expected from the temperature. This point may be helpful, but in dealing with children it is not easy, owing to their excitability, to get their pulse-rate unless considerable time is first spent in making friends with them.

Should articular rheumatism occur about the sixth or seventh day of the disease it is very strong evidence of scarlet fever, but, as a matter of fact, in the class of case under discussion it seldom arises.

The pinhole desquamation of scarlet fever is often sufficiently pronounced to settle the diagnosis, whereas any desquamation that takes place in German measles is seldom more than powdering. In scarlet fever some slight powdering commences on the face about the third day of the disease, but pinholing is exceptionally seen. Then on the fifth, sixth, or seventh day or thereby pinhole desquamation commences about the lower neck, upper chest, or pubis, and should this desquamation become well marked the diagnosis is settled. It must not be assumed that a few pinholes scattered here and there are sufficient to found a diagnosis upon. Occasional ones may sometimes be seen in German measles and other conditions—for example, counter irritation may produce them; and, indeed, limited pinholing may be occasionally seen on an apparently normal skin. To warrant a diagnosis they must cover a fair area of skin and be numerous. Unfortunately a goodly number of cases of scarlet fever, and particularly the mild ones, do not show pinholing; and, indeed, in some no apparent desquamation occurs at all. The desquamation that occurs on the hands and feet in scarlet fever comes somewhat late to be of much value, yet it serves in helping to clear up the case, but this desquamation may be due to some other cause, particularly on the feet. Nephritis arising from the seventeenth to twenty-fourth day of the disease, or thereabout, will make the diagnosis of scarlet fever clear, especially if associated with desquamation on the hands and feet.

Measles and Scarlet Fever.

There is seldom much difficulty in distinguishing between scarlet fever and measles, and when doubt arises it is nearly always in the invasion stage of measles, especially when the case presents a scarlatiniform prodromal rash.

The onset of measles is usually gradual; there is seldom vomiting; no sore throat except perhaps a scrapy and dry feeling; there are catarrhal symptoms, cough, injection of the ocular conjunctivæ, possibly sneezing, and there is a varying degree of œdema of the skin of the face. These catarrhal symptoms become gradually more pronounced hour by hour in the invasion stage. In scarlet fever the onset is often sudden; there is usually vomiting, sore throat, and no catarrhal symptoms worthy of note. Occasionally a scarlatiniform prodromal rash appears in the invasion stage of measles; this is usually short lived, and the maculation is very indefinite, but it is usually accompanied by the aforementioned symptoms of measles which rule scarlet fever out of court.

It is true that sometimes a case of measles will be met with which has none of the usual symptoms and has a scarlatiniform prodromal rash; but even then Koplik's spots will almost certainly be present and will clinch the diagnosis. They are usually to be seen two or three days before the true measles eruption appears, and they neither occur in scarlet fever nor, I believe, in any other disease. They may appear four days or more prior to the measles rash, but occasionally only the day before, and provided careful examination be exercised they can practically always, if not always, be found. When looking for these spots it is essential, in most instances, to have a good light shining on the point under observation, and it is often necessary to raise and depress the point of the tongue depressor so as to move the mucous membrane and thus get the glint of light necessary to cause the bluish-white dots to be seen more readily.

When first seen the spot consists of an irregularly rounded small patch of a bright red colour showing on its centre a bluish-white dot. Usually these rapidly increase in number, and the red areolæ round each dot joins other areolæ until the mucous membrane is for the most part, or entirely, brightly injected, and shows scattered over it innumerable bluish-white dots. Occasionally, however, the mucous membrane will be found brightly injected all over when first seen and no bluish-white dots visible; but a second examination in a few hours, at most 24, will disclose them. When they are so numerous as I have suggested they are usually readily seen in a good light unless they are exceptionally tiny; but though they are ordinarily numerous they are not always so and occasionally only a very few are to be found. If few in number, the most likely place to find them is on the buccal mucous membrane opposite the molar teeth, but should they not be found there a lengthy search is often necessary.

I sometimes find that an exaggerated idea of the size of these bluish-white dots exists. A large size would correspond to the head of a small pin, provided there has been no

coalescence, a small to the point of the same, and naturally intermediate sizes are more usual. I have not found them on the gums, the tongue, or on the hard palate, but on a few occasions I have seen them on the soft palate. If a very large crop of them is present on the buccal and labial mucous membrane it is not uncommon for some to coalesce and thus form larger spots; but, even then, if one is well acquainted with the Koplik spot, there is no possibility of confusing it with any other condition.

When the measles rash has commenced to appear, or is fairly well developed, confusion with scarlet fever is most improbable. The character of the measles rash, its appearance in the circumoral area, behind the ears, on the forehead near the roots of the hair, &c.; the absence of sore throat; the catarrh and Koplik's spots all make the diagnosis easy. It is true that Koplik's spots often disappear soon after the measles rash appears, but they are usually present for the following 24 hours, and I have seen them persist for four days after the appearance of the rash.

Occasionally a case of scarlet fever is mistaken for measles owing to a patchy eruption of the extremities, particularly on the arms. This is an error that should scarcely be made since the normal rash of scarlet fever will be present on the trunk and other symptoms will almost certainly be found, for these are usually well-defined cases.

In scarlet fever about the eighth day or later a morbilliform rash may appear, but this is a septic rash occurring in certain cases of scarlatina anginosa. It often affects the face and entensor surfaces of the extremities, particularly the elbow and knee-joints, though it may be general. It is commonly of a deeper red colour than the rash of measles, though by no means always so. But apart from that the condition of the throat, the nasal discharge, the swollen condition of the glands of the neck, and the knowledge that such an eruption in this class of case is common puts measles out of the question.

Small-pox and Chicken-pox.

In distinguishing between the early eruptions of small-pox and chicken-pox, great difficulty may be experienced, but this is seldom so, for these two diseases show marked points of difference all of which rarely fail one.

I am tempted to think that too great reliance is sometimes placed upon the less important differences to the great detriment of the all-important ones. Nowadays, small-pox is mostly a disease of adults, chicken-pox of children, and consequently if the eruption is on an adult, a suspicion that it may be small-pox sometimes crosses the observer's mind, and may mislead him. Occasionally, a medical man meets with a very abundant eruption of chicken-pox, and that fact may suggest to him that after all the case is possibly small-pox; and this is particularly so if it happens that a few of the lesions run into others. Confluent chicken-pox, as understood, is rare, but that an occasional lesion should join another is not. Again, in adults suffering from chicken-pox, headache and backache are sometimes complained of, and this appears to be an occasional cause of error; but it is not uncommon for the adult who contracts chicken-pox to suffer from headache and backache. Also an initial erythema may accompany or precede the eruption of chicken-pox, but the character of the initial erythemas of chicken-pox should not lead one astray.

No one of these lesser points I have mentioned is of very much importance, and while noting them the observer ought not to balance them against better evidence.

The most important diagnostic point is the distribution of these eruptions, and, though not infallible, it is of such value that too much stress cannot be laid upon it; for the exceptions that occur are almost always partial. I cannot now go into the detailed distribution of the small-pox eruptions which Ricketts, in that admirable text-book on the diagnosis of small-pox by himself and Byles, so ably sets forth. The lesions are most numerous on the face, next on the upper extremities, then on the lower extremities or back. They are more numerous on the forearms than on the arms, and still more so on the hands, and in a lesser degree the same rule holds good for the lower extremities. They are more numerous on the back of the trunk than on the front and over the upper part of it than on the lower. The eruption prefers the extensor surfaces to the flexor and the prominences to the hollows and shallows.

The lesions of chicken-pox particularly affect the trunk, next the face, then the extremities, and on the extremities they become less numerous the more distal. It is true the eruption is usually more dense on the back of the trunk than on the front, but it shows no preference for the upper part of the trunk as compared with the lower. It shows no preference for the extensor surfaces as compared with the flexor, and it does not shun the shallows and hollows; indeed, in a limited eruption it is rare not to find lesions in the axillæ.

The lesions of small-pox are deep-seated, those of chicken-pox very superficial, as may be best demonstrated by picking up individual lesions between the finger and thumb where the skin is soft and loose. It is undesirable to draw the fingers across the forehead to feel for a shotty eruption, for this is not unusual in chicken-pox. In modified small-pox the lesions may be less deep-seated; and rarely the lesions of chicken-pox are not superficial, but superficial lesions will almost certainly be found somewhere. The vesicles of small-pox are usually circular, those of chicken-pox vary in shape, some being round, some irregularly elongated with the skin crease, some irregularly rounded, and even jagged. On the hands and feet the chicken-pox vesicles, if present, are very often small and round and ill-developed, whereas the lesions of small-pox are better developed on the hands than elsewhere.

The lesions of small-pox are comparatively slow in development, those of chicken-pox rapid. In small-pox they usually appear first on the face or on the backs of the hands or wrists; their appearance on the legs may be a day later, and at any given part some will be behind their fellows, but the development of all being equal, the late comers will keep their relative stage. The chicken-pox lesions usually appear first on the trunk and others follow for the first few hours. The macular stage is short-lived, and a papule is formed upon which a vesicle soon commences and is fully developed in from 6 to 24 hours, whereas even in modified small-pox vesiculation will not usually have commenced by the end of 24 hours. In chicken-pox so quickly do some of the vesicles appear that they are seen practically as soon as the macule becomes a papule, and so delicate is the covering of many of them that they quickly become ruptured by one means or another and scabs form. Since some of the macules and papules abort and some of the vesicles are arrested in their development the chicken-pox eruption in a few hours from its commencement will show the presence of lesions in most stages except the pustular. Several crops of chicken-pox eruptions may occur, but there is nearly always a second, and it usually appears about 24 hours after the original eruption, when most probably macules, papules, vesicles, their abortions, pustules, and scabs will all be present.

If a small-pox vesicle be pricked and pressed only a portion of the contents usually escapes, and it does not collapse, but in chicken-pox it commonly does; yet too much stress must not be laid upon this, for sometimes the small-pox lesions will collapse and the chicken-pox will not.

A proportion of the vesicles in small-pox are usually umbilicated, whereas in chicken-pox they are mostly dome-shaped, but sometimes in small-pox none are umbilicated, and occasionally a false umbilication of the chicken-pox vesicle is seen. Further, flat-topped vesicles are occasionally seen in both diseases.

Tottenham, N.

THE ROYAL SANITARY INSTITUTE.—A provincial sessional meeting of this society will be held at Manchester on March 8th and 9th. The meeting on Friday, March 8th, will be held in the Municipal School of Technology, Sackville-street, Manchester, at 7.30 P.M., when discussions will take place on the Application of the Housing and Town Planning Act to the Re-development of Suburban Areas now in Process of Transition, to be opened by Mr. F. W. Platt, the building surveyor of Salford; and the Quantity of Water Available from Upland Drainage Areas, to be opened by Professor J. Radcliffe. On Saturday, March 9th, the new service reservoir at Heaton Park and the new lake will be inspected under the guidance of the resident engineer. Those wishing to be present at the discussions or visits should send their names to Professor J. Radcliffe, M.Sc., Municipal School of Technology, Sackville-street, Manchester, or the secretary of the institute, not later than March 5th.

CYSTITIS: ITS CAUSES AND ITS TREATMENT.

BY DAVID NEWMAN, M.D. GLASG., F.R.F.P.S. GLASG.,
SURGEON TO GLASGOW ROYAL INFIRMARY.

(*Concluded from p. 496.*)

Treatment.

IT is very evident that, cystitis being due to so many different causes, the treatment must be regulated by a careful consideration of all the etiological factors involved. A cystitis resulting from a descending infection from the kidney cannot be remedied before the renal affection is cured. The removal of a stone, the dilatation of a stricture, or the excision of an obstructing prostate may be all that is required to deal successfully with a secondary cystitis. But when the cystitis is the cause of all the trouble, or the primary factor has been removed or dealt with, certain measures may be adopted according to the nature of the infection, the symptoms which present themselves, and the stage of the disease.

I. *Mild Bacillus Coli Infection.*

Mild bacillus coli infection of the bladder leading to juvenile incontinence or involuntary nocturnal micturition in children, and the cystitis so commonly met with during and after pregnancy, may be first considered.

When the case comes under observation at the onset, and the condition is fully recognised, the treatment is usually successful.

(*a*) *Internal medication* has for its objects to lessen the irritation of the vesical mucous membrane as rapidly and effectively as possible, to hinder the propagation of the infective organisms, and to clear them out of the bladder, for if this is not effectively done there is always liability to recurrence.

The first object is accomplished by rest, hot applications, and by rendering the urine as bland and dilute as possible. Large quantities of fluids are taken: barley water, flaxseed tea, and drinks containing acetate and citrate of potash. To allay pain and spasm the hips should be well raised on a hard pillow, in order that the abdominal viscera and the contents of the bladder may gravitate so as to relieve pressure on the neck of the bladder as much as possible, and the rectum should be kept empty by giving confection of sulphur and confection of senna in equal parts as a laxative. Phenacetin and extract of hyoscyamus may be given internally in 5 grain doses, and if the pain is very acute and vesical tenesmus is present a rectal injection of two teaspoonfuls of starch containing antipyrin and laudanum may be administered. Urinary antiseptics should not be employed in the acute stage as they are too irritating.

(*b*) The administration of *urinary antiseptics* by the mouth and local applications to the bladder are not suitable during the acute stage, but as the inflammation declines treatment should be directed to reducing the activity and power of propagation of the micro-organisms, and in the end rendering the urine aseptic.

For this purpose the administration of boric acid is most useful when the inflammation is limited to the bladder, but when the kidneys are also involved the drug is not tolerated—it at once upsets digestion. Helmitol is better than urotropine, but the action of both must be carefully watched as their action varies greatly in different cases. Sometimes they suit admirably for a time, and then suddenly they act as irritants. The ammonia salts of formaldehyde, if administered for a length of time, are liable to act in this way. In cases where the urine is acid, as in bacillus coli infections, formalin is liberated from these preparations and creates irritation, but if the urine be rendered neutral or alkaline by potash or lithia salts this difficulty is overcome.

(*c*) *Local applications* in these milder forms of infection are as necessary as in the more virulent diseases, but less powerful methods are called for. If employed within a short time of the onset of the infection irrigation with boric acid solution, quarter strength, that is to say, one part of saturated solution to three of sterile water, is most useful if the washing out is thorough. The bladder should be fully but not overdistended four times at each washing, and this should be repeated every second day till the urine passed on the second day fails to give growths on cultivation or infection by inoculation of animals. Unless these tests are applied we have no guarantee that the patient is safe.

In cases which have become chronic, as in children who suffer from involuntary nocturnal micturition, and women who complain of frequent and painful micturition as a consequence of inflammation of the neck of the bladder or the urethra, local treatment is required over and above what has been described.

In involuntary nocturnal micturition not due to extrinsic causes, the neck of the bladder or the urethra is usually congested. This may be cured by careful instillations of nitrate of silver 1–2 grains to the ounce, after washing out the bladder with sterile water and emptying it. In a child 3 ounces may be injected and left in the bladder. As soon as urine flows into the bladder the silver salt becomes combined with chlorides and forms an insoluble salt.

When the vesical end of the urethra or the mucous membrane of the canal is involved the duct should be dilated freely, a speculum introduced, and the whole passage swabbed with pure phenol, and immediately washed with a solution of bicarbonate of soda to check the action of the carbolic acid. The pain that follows is sometimes severe for the first few days, but is easily relieved by cocaine bougies or morphine, and generally in a week or ten days all the old troublesome symptoms have disappeared.

II. *Acute Cystitis.*

The treatment of the severer forms of acute cystitis due to pneumococcus, streptococcus, gonococcus, or tubercle bacillus is constitutional and local. At first pain, frequent desire to pass urine, and tenesmus are the symptoms which require immediate attention. The patient must remain in bed, and the symptoms may be relieved by warm baths and sitz baths with aromatic herbs, or hot moist compresses may be kept on the abdomen. Diet should be plain and the quantity limited, and, as indicated above, bland fluids should be given in considerable quantity. The drugs given must depend upon the reaction of the urine, but in all cases phenacetin and extract of hyoscyamus—for an adult 5 grains of each three times daily—should be taken. Opium should be avoided, but morphine may be given hypodermically if demanded on account of the pain. The bowels must be kept free but not purged, except once at the onset, with calomel, followed by a saline.

The reaction of the urine determines the other drugs prescribed. The excretion should be kept as nearly neutral and as dilute as possible. Great quantity of fluid does not lessen the frequency of urination, but it lessens the pain and washes out the bladder from above, when washing out from below is inadvisable. The more frequently the contents of the bladder are changed the less toxic the urine is rendered. It is when the excretion suddenly diminishes that dangers of sepsis may be looked for.

As early as possible the organisms producing the attack should be isolated and a vaccine prepared from them and administered as soon as convenient. If they are found to be urea-decomposing organisms every endeavour should be made to keep the urine acid, but if they are pure cultures of bacillus coli, tubercle bacillus, or streptococcus pyogenes, alkalies or salts, which reduce the acidity of the urine, may be freely given.

A few words may be said in regard to the use of *vaccines* in cystitis, but, while admitting the value of this treatment, it must not be employed to the neglect of other general and local remedies. The preparation of vaccines and the mode of determining the opsonic index cannot be considered here. The vaccines are standardised emulsions of microbes, sterilised, in 1 per cent. saline solution, and when injected subcutaneously produce active phagocytosis and an antimicrobic substance which induces a process of immunisation which may be gauged by what has been called the "opsonic index." This term, introduced by Wright, is very convenient for expressing the phagocytic activity of leucocytes in an infected individual as compared with a normal man, but the process is so complicated and the danger of error so considerable that it is very doubtful if these estimations are of the value placed upon them by their author, perhaps with the exception of observations in tuberculosis.

Not infrequently, while waiting for the vaccine to be prepared, marked progress towards recovery may be obtained by the older therapeutic methods Having adopted the general instructions referred to, doubtlessly they may be aided greatly by giving auto-vaccines procured from cultures

of the organisms giving rise to the cystitis. But as the preparation of the auto-vaccine involves a delay of five to six or seven days, it is well to discover as early as possible the nature of the organism present, and use a stock vaccine until the auto-vaccine is ready. Stock bacillus coli vaccine is not a good substitute for an autogenous vaccine. Coliform bacteria are a family, and the number of different strains met with are so considerable that it is necessary to have special vaccines prepared to meet each individual case; in gonococcus, streptococcus, pneumococcus, and staphylococcus infections stock vaccines are satisfactory temporary substitutes for the autogenous vaccine.

Vaccines are of special value in acute cases, and should be used at once. A few years ago it was regarded as necessary to regulate the dosage by the opsonic index, but now the practical surgeon can not only look upon, but he may call the opsonic index a bogie, without being dubbed a heretic. The dose of vaccine and the frequency of administration, like any other therapeutic measures, must be regulated by the individual case. Small doses—5,000,000 or less—at one time and repeated every three or four days in acute cases give the best results. In chronic cases, to begin with, the same doses may be given, and gradually as time passes the dose may be increased and the intervals prolonged until 40,000,000 or 50,000,000 are being given once a fortnight. The vaccine should be continued until the urine is sterile, as proved by cultures and inoculation. The cure must not be judged by the disappearance of symptoms only; if it is, a relapse is likely to occur. In tuberculosis the opsonic index is of value, and when possible should be employed in treatment by tuberculin, but not having means to ascertain the opsonic index should not prevent the surgeon giving the patient the advantage of this treatment. Of tuberculin R., the strength of which is such that 1 c.c. represents 10 mgm. of dried bacilli, a small dose should be given at first—e.g., 0·00001–0·00002 mgm. of dried bacillary substance, and this may be gradually increased to ten times the amount according to circumstances.

As regards *local treatment*, what has been said in respect to the treatment of bacillus coli infection applies here—only stronger remedies are demanded. The idea in using germicides in cystitis is not to kill all the organisms at once but to reduce their virulence, and as far as possible their power of multiplication. To use drugs of sufficient strength to destroy the cocci would seriously injure the living tissues. The following remarks apply to all infections other than tuberculous—it will be considered separately.

In acute cystitis the local treatment consists of *irrigation* and *instillations*. Both are employed with the purpose of getting rid of the organisms that have gained access to the bladder, the former by washing them out, the latter by destroying the infective matter and acting as a remedial agent to the mucous membrane. In all cases of infection of the bladder what we aim at in employing irrigation is thorough cleansing with a mild germicidal drug such as permanganate of potash, protargol, or argyrol in order to lessen the activity of micro-organisms. It is impossible by means of local applications to sterilise the bladder, as the agents to do this would require to be so powerful that they would irritate and injure the mucous membrane and do harm instead of good. The bladder should be emptied and for the first two or three irrigations washed simply with warm sterilised water, then gradually solutions containing one of the drugs mentioned may be employed—permanganate of potassium (1–2000), protargol or argyrol (3 to 5 per cent. solutions), boroglyceride (5 per cent.)

For instillations in recovery from acute cystitis weak solutions of nitrate of silver are the best, 1/10 grain to the ounce, gradually increased to ½ grain to the ounce; later oxycyanide of mercury in weak solutions, 1-4000, will be found of great value. Local treatment will be referred to later when considering the question of chronic cystitis, but here it may be stated that irrigations or instillations must be continued so long as any organisms are found in the urine, otherwise recurrences are liable to occur or a chronic catarrh become established.

When acute cystitis comes on in the course of a chronic affection of the bladder or in a weak elderly patient arising from any cause, but especially when there is urinary obstruction due to tumour, calculus, enlarged prostate, or urethral stricture, the condition may become very serious suddenly, and require prompt treatment to avoid general sepsis. Clearly the first indication is to relieve the obstruction and give free exit to the urine, and this should be at once done by establishing a suprapubic drain. The acute inflammation of the bladder must be allowed to subside before any attempt is made to deal with the other conditions present. Suprapubic cystostomy when performed early is such a safe operation, and so immediately followed by relief of symptoms and release from danger, that in such cases there should be no hesitation in resorting to it.

Chronic Cystitis.

Chronic cystitis is generally associated with incomplete evacuation of the bladder, so the first essential point to attend to is to see that its contents are emptied at regular intervals and that the source of obstruction is removed.

The whole condition of the individual case must be carefully considered. In some instances a cure may be effected by prolonged constitutional and mild local treatment, in others the sooner a suprapubic drain is established the better. In the former the whole life of the patient must be carefully regulated. Diet must be simple and moderate in amount, exposure to cold and wet, travelling, riding, cycling, or much active exercise must be avoided. Fluids should be taken in good quantity and milk diet adhered to three days a week, and stimulants, unless in exceptional cases, are not admissible. Saline and sulphur baths are useful, and the administration of infusions of uva ursi, pareira brava, or triticum repens, in doses of 8 ounces three times daily, so long as the digestion is not disturbed is advisable.

Internal remedies are not of much service if we except boric acid and helmitol, or a combination of boric acid and benzoate of soda. When the urine is acid alkalines and alkaline salts are indicated, but when it is alkaline the administration of drugs has no influence upon its reaction, which is due to decomposition of urea in the bladder.

A cystoscopic examination having demonstrated the lesion present, suitable local treatment must be employed in combination with the general treatment above indicated.

(*a*) Cases of uncomplicated chronic cystitis due to an *organism which does not decompose urea* are best treated by regular irrigation; simple withdrawal of the urine is not sufficient. In infection by bacillus coli frequently the bladder wall is coated with flaky mucus which adheres firmly to the mucous membrane, and this must be washed away by irrigating the bladder very freely morning and evening *regularly*. Regularly, because if the irrigation be interrupted before the bladder is thoroughly cleansed the bacilli have an opportunity of reasserting themselves. Distend the bladder as fully as possible short of producing pain, and empty it from four to six times at each sitting. This must be done by the surgeon, not by the patient, however practised he may be in the use of the catheter, and with a syphon arrangement. Syringes are no use.

If a patient is lying upon his back or even standing, and say 12 ounces of fluid is introduced by a syringe and the fluid allowed to escape through the catheter, not nearly the whole of the fluid may come away; but if the catheter is continuous with a syphon tube with a 2-foot fall, not only will the bladder be completely emptied but the solution will be withdrawn rapidly and with suction, and the cleansing thereby rendered more thorough. Besides, by using a syphon the pressure employed is known; with a syringe it is impossible to judge the force employed.

The simplest plan is to have the first limb of a T-tube fixed to a gum-elastic catheter; from the second limb of the T have a clipped rubber tube leading from an irrigator elevated 2 feet above the bed to give ingress pressure; and to the third limb have a clipped rubber tube falling to a vessel on the floor, which will give an egress suction of a 2-foot fall. Fill the tubing and catheter with solution, close the ingress tube with a clip, and then, having introduced the catheter into the bladder, open the clip which allows the contents to escape, but do not empty the bladder, as it is liable to cause irritation. Then close this clip and open the ingress tube, distending the bladder till the patient complains; then allow the solution to flow out into a glass vessel, and repeat the irrigation until the fluid escapes perfectly clear. This is repeated morning and evening until the urine passed naturally is sterile.

A cystoscopic examination should then be made, and if irritation be noticed at the neck of the bladder one or two instillations of nitrate of silver by means of Guyon's catheter may be given. The bulb of the catheter is passed beyond the grasp of the compressor urethræ, and a 1 per cent. solution of nitrate of silver is slowly passed in until 20 to 30 drops have been injected. They are allowed to remain, and their action is soon neutralised by the salt in the urine.

(*b*) When the cystitis is due to *organisms which decompose urea* the carbonate of ammonia formed renders the urine very irritating and offensive, so that the bladder and urethra are less able to tolerate active local treatment than in the cases above described. Consequently great care is required in the selection of the agents to employ, in fear that the irrigation in place of relieving the condition may aggravate it. Probably the best agent to use to begin with is permanganate of potash 0·025 per cent., and gradually increasing to 0·1 per cent. solutions. At first the bladder may only admit a small quantity. In such instances continuous irrigation for ten minutes through a double catheter is most useful, the ingress irrigation being raised to 2½ feet and the egress vessel to 1½ feet, so that the fluid within the bladder is submitted to a constant pressure of a little over 1½ feet column of fluid. This may be repeated daily.

When the urine is alkaline after irrigating an instillation of pure lactic bacillus cultures in milk whey or the filtrate of saurine may be employed with great advantage. By setting up an acid fermentation the urea-decomposing organisms are weakened or destroyed and the phosphates dissolved.

If irrigation improves the condition of matters, the micturition becoming less frequent, the urine less purulent and offensive, and the general health of the patient more satisfactory, then other agents, such as boric acid, acetate of lead (1–2000), or nitrate of silver 1/12th grain to the ounce, may be used with advantage, and finally instillations of a stronger solution may be employed.

Notwithstanding careful local and general treatment, a certain number of cases of chronic cystitis persist, especially in those in which there is residual urine, or in which the kidneys are involved in the infection. In these, continuous drainage by tying in a catheter has been recommended by some surgeons, with the precaution that a soft rubber instrument should be used, removed daily and sterilised and reintroduced. Beneficial results are sometimes obtained, but more commonly the urethra becomes intolerant of the catheter and the treatment is discontinued.

Often in these patients the cystitis has led to an inflammatory enlargement of the prostate, and the contents of the bladder are found to be so viscid that they will not flow through the catheter or wash out with the irrigator. When this is so, or when there is hypertrophy of a muscular coat and sacculation, stone or tumour, a *suprapubic drain* must be established to give free exit to the contents of the bladder and allow of thorough cleansing. A temporary drain of this kind is by far the most effective treatment of chronic cystitis, and even in the most persistent and intractable cases astonishing results are obtained. Not only does the urine become healthy and the mucous membrane normal, but large, inflamed, softened prostates subside, and in a few weeks the wound may be allowed to close. In many cases this inflammatory enlargement is liable to be mistaken for hypertrophy of the prostate, and the danger is that the prostate may be excised when a cure might be effected by drainage alone. The drainage employed is by syphoning the urine into a suitable vessel so as to permit the patient to go about with freedom. The method used for the last nine years[1] is easily carried out and has been very successful.

In cases in which it is necessary to drain the bladder for a considerable period it is a great comfort to the patient to be able to move about unhampered by bulky and often soaked dressings. When such dressings are used the patient is not only hindered from following his occupation, but on account of the offensive odour necessarily connected with them he is precluded from associating with his fellows. Direct drainage by syphoning the urine into a suitable vessel permits the patient to go about with freedom, the skin and clothing are kept dry, the patient is not incommoded by the constant changing of dressings, and considerable expense is saved.

Take, for example, a case in which for chronic cystitis from infection with staphylococcus pyogenes aureus suprapubic cystotomy has been performed. At the operation a large drainage-tube in inserted through the wound into the bladder. The following day to the outer end of the rubber tube a glass T-tube is fixed and kept in position by a shield of block tin. To protect the skin a fold of gauze is placed below the shield, and over it a firm belt or bandage to keep it in position. To the upper limb of the T-tube a short length of rubber tubing is attached and to the lower limb a tube about 3 feet long. This tube is carried to a glass tube, which passes through a rubber cork to the bottom of a small wash-out cistern which has been nearly filled with boric solution. By fixing an empty syringe to the short length of rubber tubing and exhausting, the fluid from the cistern is drawn up to fill the rubber tubing, when the short tube is clipped. The cistern is fixed to the side of the bed, giving the fluid a fall of about 14 inches. When the cistern is filled above a certain level the syphon action comes into play, and the cistern empties its contents through a tube into a vessel placed on the floor. For the first week a small dressing is required, and may be changed once daily if soiled. When the wound has healed and the patient is able to be out of bed the wash-out cistern should be replaced by a flask.

An "Alexandra" baby's feeding-bottle with a rubber stopper answers admirably. The lower tube is fitted to the tube in the flask, which is turned up at the lower end so as to prevent air entering and the tubing becoming empty, when it is withdrawn from the flask. When the patient is going about the flask may be carried in a hip-pocket, or if this is inconvenient its place may be taken by a rubber urinal.

This drainage must be supplemented by careful irrigation, and if the urine is alkaline, or contains alkaline phosphates after irrigating, an instillation of lactic bacillus cultures should be given. Milk whey containing pure lactic bacillus not only destroys the septic organisms in the bladder but also dissolves phosphatic crusts adhering to the bladder or the wound. The filtrate of saurine does admirably and may be used with advantage in all purulent conditions. A suppurating sac or a granulating surface thoroughly washed regularly with it cleans up rapidly; it acts more satisfactorily than any chemical antiseptic, and the lactic acid bacillus not being a pathogenic organism does no harm. In some cases quite remarkable results have been obtained.

In very contracted bladder it is difficult to expose the organ, and a considerable thickness of wall requires to be cut through before the cavity is reached. But when the source of irritation is removed and free exit given to the urine it is astonishing how soon the bladder becomes capable of distension. In cases where with the finger through the suprapubic wound the bladder felt like a hard ball with a cavity of the size of a walnut, the patient has ultimately been able to retain from 12 to 15 ounces of urine, and micturated not more than four or five times in 24 hours.

(*c*) Cystitis consequent on *infection by tubercle bacillus* is in almost all cases secondary to tuberculous nephritis, and so long as the kidney is excreting infected urine into the bladder no treatment of that organ is of any avail. First to be considered are those cases where both kidneys are involved or where the affected kidney cannot be removed; secondly, cases in which nephrectomy can be done; and thirdly, those rare cases of primary vesical tuberculosis.

The first category are very hopeless, and all we can do is to alleviate suffering. So long as the infection is pure the symptoms are not very severe, but when it becomes mixed—namely, both tuberculous and septic—general cystitis is set up, and adds greatly to the seriousness of the disease and the suffering of the patient. Hence the employment of the catheter must be undertaken with a full sense of the responsibility involved in keeping the bladder thoroughly aseptic. These cases are unusually liable to infection, and it is very questionable if benefit should be sought from local treatment so long as the urine remains acid.

For the relief of pain morphine or belladonna suppositories are useful, and phenacetin and hyoscyamus given internally are most effectual. In those hopeless cases of general cystitis caused by mixed infections often the continual pain and constant desire to micturate can only be relieved by cystotomy and drainage. Of course, in such instances no attempt can be made to remove the disease.

[1] A Method of Draining the Kidney and Bladder, Glasgow Medical Journal, September, 1907.

In tuberculous cystitis secondary to unilateral renal infection, after nephrectomy the bladder condition may heal spontaneously. At all events, in such cases the primary affection must be dealt with first. Supposing the kidney has been removed and some months have been allowed to pass but still the bladder condition remains troublesome, and the cystoscope shows little or no improvement in the appearances, what should be done? It is taken for granted that general constitutional treatment has been carried out: tuberculin R used, regulated by the opsonic index, tonics, iron, strychnine, cod-liver oil, and urinary antiseptics have been prescribed; the patient has had the advantage of open-air treatment and regular dieting. Instillations and irrigation have not given encouraging results and often do harm.

The perchloride of mercury has certainly done good in some cases, but in the majority the effect has been harmful. Lactic acid, pyrogallic acid, creosote, and nitrate of silver are of no value as remedies. Guaiacol along with iodoform mixed in oil, 2 to 3 per cent., is most useful of any, but probably the best results are got by introducing four ounces of sterilised olive oil, or an emulsion of iodoform in olive oil, and instructing the patient to micturate standing until he notices the oil coming away, and then to stop. Some of the oil remains in the bladder, generally for 12 or 18 hours, and certainly helps the healing process. The injection may be repeated every day, and the bladder should be well washed out prior to the introduction of the oil.

Rovsing has reported good results from the injection of 100 c.c. of a 0 5 per cent. solution of carbolic acid in water. He allows it to remain in for five minutes, then draws it off through the catheter. The writer also has had good results from this treatment, better probably than from any other. But it must be combined with complete rest in bed.

Should time pass and still cure be delayed, four courses are open: (1) Instillations of perchloride of mercury; (2) curetting the bladder, in the female per urethram, in the male through a suprapubic opening; (3) injection of 2 per cent. thallin sulphate; and (4) suprapubic drain.

There is no doubt perchloride of mercury 1–20,000 to 1–10,000 parts of sterilised water produces a very beneficial result, and certainly warrants a fair trial. But as it occasions considerable pain the patient is often unwilling to give the treatment a chance. To use cocaine or other local anæsthetic before the instillation is inadvisable, but a subcutaneous injection of morphine or a general anæsthetic may be used. The instillation of half an ounce of the solution should be administered every third day on three occasions, then discontinued for a fortnight, the patient being kept at rest but not in bed. Nitrate of silver instillations should never be used.

Curetting the tuberculous ulcers or nodules through the urethra in the female, or a suprapubic wound in the male, often helps matters very much, and the establishment of a suprapubic drain gives the bladder rest and free exit to the urine, and at the same time the viscus can be carefully and regularly douched, either with weak boric acid solution, 0·5 per cent. solution of carbolic acid, or 2 per cent. thallin, and the ulcers may be swabbed with pure phenol through a speculum, and the action of the agent checked by washing afterwards with a solution of bicarbonate of soda.

The following statistics collected by Walker are of interest[2]:—

Summary of Walker's Statistics.

Climatic or medical	18	6	—	12	—	—
Total	95	9	—	54	26	6

The above statistics date from 1907, and hence do not give the best results now obtainable. The diagnosis can now be made at the beginning of the disease, and the primary focus of infection in the kidney can be removed at an early date in the history of the malady. If this be done, followed by free drainage and complete rest of the viscus for several weeks, together with the administration of tuberculin R., with the dosage regulated by the opsonic index, there is some hope that vesical surgery will be elevated out of the pitiful position it not long ago occupied in relation to tuberculosis of the bladder. Until five years ago cystostomy was employed in the late stages of the disease only, when the patient was tortured by pain and frequent micturition. While in such cases it undoubtedly gave marked relief of the symptoms, from the very nature of the conditions present the operation could not be expected to be a curative one. Now, when attacked early—namely, while the mucous membrane alone is involved, as demonstrated by the cystoscope—cures may be obtained. The writer intends publishing at an early date cases in which perfect healing has taken place, and the patients are now alive and well.

Glasgow.

TWO CASES OF

VOLVULUS COINCIDENT WITH STRANGULATED HERNIA.

BY FORBES FRASER, F.R.C.S. ENG.,
SURGEON TO THE ROYAL UNITED HOSPITAL, BATH.

CASE 1.—The patient was 55 years of age and had for years been the subject of a large inguinal hernia. After a hearty supper on the evening of March 13th, 1910, he had sudden pain in his abdomen and vomited several times. The vomiting brought down the hernia, and he was unable to get it back. During the night he had violent diarrhœa and more vomiting, and early next morning he was admitted to the Royal United Hospital.

When I saw the patient there he was complaining of severe abdominal pain, and was constantly vomiting bile-stained fluid without fæculent odour. He looked pinched and ill, his pulse was weak (100 to the minute), and his temperature 99·2° F. There was present a very large right scrotal hernia, obviously strangulated. His abdomen was moderately distended, tender, and rigid, but no swelling could be felt.

Operation was performed 14 hours after the onset of the symptoms. An incision was made over the sac, which contained much dark-brown foul-smelling fluid. The bowel was dark and ecchymosed. A constriction at the neck of the sac was divided, and on pulling down the intestine its condition above the site of strangulation was found to be no better than that below. Coil after coil of black swollen bowel was pulled down, till the origin of the trouble was found to be in a twist which had occurred 3 inches from the ileo-cæcal valve. At this situation a loop of ileum had formed a half-turn on itself from left to right, and here both limbs of the loop were completely gangrenous. The peritoneal cavity contained a large quantity of blood-stained fluid. It was felt that the only chance of recovery lay in the complete removal of the volvulus, so the wound was enlarged upwards and the whole resected. The method used was that which has been described by Barker, the divided distal end of the portion

of bowel about to be removed being allowed to hang over the side of the table and syphon off its contents into a pail while the mesentery was being ligatured off. The divided ends were then closed and a lateral anastomosis was made between the remains of the ileum and the cæcum. A drain was left in the neighbourhood of the junction and the wound was closed. Three pints of saline solution were infused into a vein while the operation was in progress. The portion of ileum resected was found to measure 7 feet in length.

The patient made an uninterrupted recovery, the bowels acting naturally on the third day. During his stay in the hospital he generally had one loose action of the bowels every day, and the restoration of his strength did not appear to be in any way retarded by the loss of so large an area of absorbent surface.

CASE 2.—The patient, a woman, 74 years of age, was admitted to the Royal United Hospital in February, 1911, with a history of complete intestinal obstruction and abdominal pain for eight days, and of vomiting for two days before admission. About a year before she had suffered from an abscess in the right groin, which healed up after being opened.

On admission the patient was drowsy and flushed, with a pulse of 96 and subnormal temperature. She was vomiting fæcal-smelling liquid. Her abdomen was much distended, and visible peristalsis was present. Nothing could be felt per rectum. There was a scar in the right groin, with a soft indefinite swelling under it, which was not particularly tender and did not give one the impression of being a hernia.

The diagnosis was intestinal obstruction, probably due to growth. The abdomen having been opened in the middle line, the small intestine was found to be distended, and the cæcum and colon collapsed. A coil of distended ileum was traced down to the neighbourhood of the right femoral canal, close to which it was found to be twisted on itself and to be the site of obstruction. The extremity of the coil protruded into the femoral canal, where it was strangulated in part of its circumference. A second incision was made over the femoral ring and the sac of a hernia opened. The strangulated coil was freed and returned to the abdomen, where it was untwisted and wrapped in gauze. The hernial sac also contained a densely adherent appendix vermiformis, which on being removed was found to have its lumen obliterated. In all probability the history of "bubo" was to be explained by the occurrence of an appendicular abscess in the sac of the hernia. After radical cure of the hernia, on returning to the abdomen it was found that a patch of gangrene was present where the bowel had been caught by the femoral ring. This patch was inverted, and, the rest of the intestine being in good condition, the wounds were closed.

This patient also made a satisfactory recovery, save that after the stitches had been removed on the tenth day she extruded her intestines through the wound during a fit of coughing. The extruded coils were at once cleansed and returned and the wound re-sutured, and she appeared to be little the worse for the accident.

Remarks.—These two cases are examples of the combination of volvulus with strangulated hernia, to which attention has been called in recent years by several writers, notably Knaggs,[1] Dobson,[2] and Miller.[3] They form a very marked contrast in the severity of the symptoms which may be met with in cases of this kind, where conditions exist which, though anatomically alike, differ both in degree and in mode of production.

In the first case it is, I think, clear from the history that the volvulus was the primary trouble, and that the strangulation of the hernia was produced by the vomiting and by the swelling of the affected intestine consequent on this. The amount of intestine involved being very large, the mesenteric blood-vessels were immediately occluded by the twist, with the result that in little more than 12 hours after the onset of symptoms the intestine was reduced to a condition in which complete excision became necessary to save the patient's life.

In the second case, on the other hand, there can be little doubt that the pinching of part of the circumference of a loop of ileum in the femoral ring was the primary trouble. The strangulation not being very tight the vitality of the bowel was not immediately endangered, and probably owing to peristaltic movements and the fixation of the bowel at this point the volvulus occurred secondarily. As only quite a small loop was involved the blood-supply was not entirely cut off, but complete obstruction of the bowel was produced by the pressing together of the limbs of the loop at the point where the twist took place. The result was that after eight days' obstruction the condition of the second patient was better than that of the first at the end of 12 hours, and a simple operation was sufficient to remedy the trouble.

In neither case was a correct diagnosis made before operation. In the second case probably this was excusable, but in looking back on the first case one feels that the gravity of the patient's condition only 12 hours after the beginning of his illness ought to have suggested that behind the obviously strangulated hernia some further and more severe cause of trouble might be in existence.

With regard to the successful issue after so extensive a removal of intestine, I think one may attribute it in the first instance to the continuous intravenous infusion of saline throughout the operation, which was kindly carried out for me by colleagues at the hospital; and, in the second place, to the use of that most valuable device, described by Barker, of using the whole length of the intestine about to be removed as a syphon, whereby large quantities of septic fluid can be drained off from the obstructed bowels.

In the excision of inflamed or gangrenous intestine it appears to me that one of the most important points, and one to which sufficient attention is not given in text-books, is the treatment of the mesentery. This structure, in all cases of which I have personal experience, is enormously swollen and œdematous and its vessels are engorged with blood, with the result that severe hæmorrhage is apt to occur when the clamps are removed after it has been divided. Such loss of blood, in addition to the already grave shock associated with these operations, is, I believe, sufficient sometimes to turn the balance against recovery.

To avoid this hæmorrhage as far as possible the mesentery should, as recommended by Barker, be first folded on itself and clamped in its whole length, parallel to the long axis of the intestine to be removed, with long powerful clamps (pylorectomy clamps answer admirably). The bowel is then cut away from the mesentery, and while the divided lower end of the part to be removed is syphoning off its contents, the whole mesentery is ligatured off, distal to the clamps, by interlocking sutures, passed through both leaves and back again with a large straight needle carrying stout linen thread. In order to interlock the sutures the second must be passed before the first is tied, the third before the second is tied, and so on to the end.

Even after carefully ligaturing off the whole margin in this way bleeding may still be found to occur from a few points after removal of the clamps, owing either to the failure of the ligatures to sufficiently compress the large vessels in the swollen mass of tissue or to some of them having cut through portions of it. These points can, however, easily be tied separately.

The ordinary method of a simple running or blanket suture along the divided margin of the mesentery is useless in such cases, and if depended on will lead to severe loss of blood the moment the clamps are removed.

The interesting question as to how far nutrition suffers in persons who have lost a large portion of their small intestines is answered, in the case of my patient, by a letter received from him in January last—i.e., 1 year and 10 months after the operation. He states that his health and appetite are good, and that it makes no difference to him what kind of food he eats; that his bowels act regularly two or three times a day; and that he regularly does light work.

Except, therefore, for some looseness of the bowels this patient does not appear to be appreciably the worse for the removal of what in all probability amounted to more than half the length of his ileum.

A VAGINAL PESSARY RETAINED FOR TWENTY-NINE YEARS.

PERFORATION OF THE BLADDER AND FIXATION OF THE INSTRUMENT BY A LARGE PHOSPHATIC VESICAL CALCULUS; LITHOTRIPSY; RECOVERY.

BY A. C. BUTLER-SMYTHE, F.R.C.S. EDIN.,

SURGEON TO THE SAMARITAN FREE HOSPITAL FOR WOMEN, MARYLEBONE-ROAD, LONDON, AND TO THE GROSVENOR HOSPITAL FOR WOMEN AND CHILDREN, WESTMINSTER.

THE following case is of so uncommon a character that the notes of it will, I feel sure, be interesting to readers of THE LANCET.

The patient, a decrepit and emaciated old woman, aged 58, came under the notice of my colleague, Dr. J. A. Willett, in the out-patient department of the Samaritan Free Hospital for Women on Dec. 27th, 1911. She complained of the dribbling away of urine and of a slimy blood-stained discharge from the front passage, which she said had been going on for three weeks. On seeing that the patient had some sort of a pessary tightly fixed in the vagina Dr. Willett admitted her under my care. The following history was with difficulty elicited owing to the woman's exhausted condition. She had married at 25 years of age, and her only child had been born three years later, the labour being a bad one. The child, a girl, lived a few months. During the next few years the patient had four miscarriages at the third month or thereabouts. Some years later the womb dropped, and 29 years ago she went to a hospital and had a support inserted into the front passage. She had worn the same instrument ever since. About 14 years ago she had had it seen to, but the medical man did not remove it. She had used a Higginson's syringe regularly in order to keep the instrument clean. About two and a half years ago she had noticed that the urine was dribbling away, and that there was a blood-stained discharge from the front passage. These troubles continued for a time and then ceased. She kept on with her work until three weeks previously, when the dribbling and discharge came on again and she sought advice. Visual examination showed the vulva, the perineum, and the sacral region to be excoriated from contact with urine and discharge. Immoveably fixed in the vagina, and protruding from its orifice was seen a portion of a pessary encrusted with phosphatic deposit. The vaginal canal was so contracted that thorough examination by finger was impossible without the aid of an anæsthetic, and manipulation of the pessary failed to produce any appreciable movement of the impacted instrument.

On Jan. 3rd, 1912, an anæsthetic was administered by Dr. R. E. V. Hale, and assisted by the resident medical officer, Mr. D. W. Roy, I proceeded to dilate the vagina and remove the pessary. The vaginal tissues had overgrown the embedded sides of the instrument, and the granulations had to be dissected away. No amount of dragging on the pessary served to loosen it or draw it down; in fact, it seemed to be immoveably fixed in the upper part of the vagina, where a mass of granulations and phosphatic deposit could be made out, with a bar or limb of the instrument firmly fixed at that point. A sound was then introduced per urethram and a large calculus was detected filling the cavity of a contracted bladder. On pushing up the pessary, with the sound in the bladder, it was felt that the instrument had perforated that organ and was connected with, and probably embedded in, the calculus. It was obvious that with such a contracted bladder, no enlarging of the fistula or incising of the bladder per vaginam would allow of the extraction of such a large calculus, and the only method that could with safety be adopted was lithotripsy. A strong forceps was therefore passed alongside the limb of the pessary into the bladder and the lower portion of the stone broken up. The instrument then became loose and was extracted, free bleeding following its removal. The remaining portion of the calculus was then crushed and removed piecemeal by forceps and scoop and the débris washed out. On introducing the examining finger through the fistulous opening into the bladder it was felt that the walls were encrusted with thick phosphatic deposit which on being broken down left a granulating surface which bled profusely. The bladder was washed out again and again with hot boric solution without any effect on the hæmorrhage, but when a hot injection of hazeline was employed the bleeding promptly ceased. The vagina was then douched with iodine (℥ii. to 1 pint), and lightly plugged with iodoform gauze, and the patient removed to bed. The severity of the operative measures, which extended over an hour, must have been a great strain on the patient, and her condition at the close was not all that could be desired: However, she rallied well, and on the following morning, much to my surprise, was in a very fair condition and comparatively free from shock. With the exception of occasional hæmaturia and rises of temperature she made an excellent recovery from the operation. Later on I hope to repair the vesico-vaginal fistula.

The instrument removed was what is called Greenhalgh's bendable pessary. It is made of tough copper wire covered with rubber, and its ends are joined by soft rubber tubing. (In my opinion, it is one of the most atrocious instruments ever invented for the torture of womankind.) One limb of the pessary had perforated the anterior vaginal fornix on the left side of, and in front of, the cervix uteri, and had penetrated the bladder, the opening into that organ being large enough to admit a finger. The anterior vaginal fornix was also separately perforated, on the right side, but the pessary had not passed through the walls of the bladder. The calculus was composed of phosphates. It completely filled the bladder and was about the size of a small Tangerine orange. For how long the calculus had been in the process of formation must remain a matter of conjecture, but its commencement probably dated from two and a half years ago when the dribbling of urine and bloody discharge were first noticed by the patient. Presuming that the penetration of the limb of the pessary into the bladder occurred two and a half years ago, a curious feature in this case is the fact that the opening in that organ should have become blocked up and rendered almost watertight for such a length of time by the deposit of phosphates around the end of the pessary within the bladder, and the granulations and concretions on the vaginal surface. The caked condition of the interior of the bladder and its contracted state seemed to point to the fact that for some time dilatation and contraction of that organ must have been incomplete. Whatever happened to cause the unblocking of the fistula, and the recurrence of the dribbling of urine can only be surmised. Possibly, in sitting down, some unusual pressure was put on the protruding end of the pessary, pushing it upwards and thus partly dislodging the phosphatic deposits in the vaginal fornix and in the bladder. It is to be presumed that the individual who inserted the pessary had placed it in its correct position—that is to say, with its posterior end behind the neck of the uterus. Owing, however, to the rotting and parting of the rubber tubing the instrument had become displaced, its ends being carried forward in front of the cervix uteri, and these pressing upon the fornix eventually resulted in ulceration and perforation of the vaginal wall and of the bladder.

The pessary, together with the phosphatic débris of which the calculus was composed, are now in the museum of the Royal College of Surgeons of England.

Brook-street, W.

TWO CASES OF PNEUMONIA TREATED WITH PNEUMOCOCCUS VACCINE.

BY GRENVILLE P. JONES, M.R.C.S. ENG., L.R.C.P. LOND.

THE following notes may prove of some interest owing to the fact that the cases responded so readily to the injection of pneumococcus vaccine.

CASE 1.—The patient, a female child, aged 12, was seized with a severe rigor on Oct. 3rd, 1911, lasting for about half an hour. Previous to this she had suffered from a bad cold for the last ten days. On seeing the child for the first time on Oct. 4th her condition was as follows. Face flushed; respirations 30, short and catchy in character. Complained of pain in left side, and troublesome cough. Temperature 102° F. Physical examination showed impaired movement over the whole of the left side of the chest, together with increased vocal vibrations and moist râles. Just below the angle of the scapula was a small area of bronchial breathing, around which were some fine crepitations. The right side of the chest showed nothing abnormal. On the 6th the temperature was 103·6°, and the area of bronchial breathing had increased in size. On the 8th the temperature was 102°,

but the general condition of the patient had become much worse and the breathing was more laboured. The physical signs on the left side were unchanged, while on the right base the air entry was diminished and a small area of bronchial breathing was found just below the angle of the scapula. The child's condition remained much the same during the next few days. On the 13th the patient seemed very much worse, and at 11 P.M. 1 c.c. of pneumococcus vaccine (Parke, Davis, and Co.) was injected. On the 14th, at 8 A.M., all the acute symptoms had disappeared and the breathing was quiet and regular, the temperature having dropped to 98·6°. The patient continued to improve during the next few days. On the 20th the temperature rose to 100° and remained at this level for some days, but the general health of the patient continued to improve. On Nov. 6th an exploratory needle was inserted into the left side and pus was discovered. On the 7th I excised a portion of the sixth rib in the post-axillary line and let out about 6 oz. of very thick but non-offensive pus, the anæsthetic being administered by my partner, Mr. W. R. L. Drawbridge. From this date the patient made an uninterrupted recovery.

CASE 2.—The patient, a man aged 45, was seized on Jan. 8th, 1912, with a rigor and pain in the right side. When I first saw him on the 10th he appeared to be acutely ill. The face was cyanosed; there was a troublesome cough, with a quantity of rusty sputum; and sharp pain in the right side was complained of. The temperature was 101° F. The physical signs showed a diminution of air entry into the right lung, the percussion note being dull at the base, with a large area of bronchial breathing over the right base behind. At 11 P.M. on the same evening the patient's condition became very critical; the respirations became more laboured and there were increased cyanosis and a failing pulse. Pneumococcus vaccine (1 c.c.) was then injected. On the 11th, at 5 A.M., the patient was much improved; the respirations were quieter and easy, there was less cyanosis, the pulse was stronger, and the temperature was normal. The patient continued to improve daily.

From a careful observation of these two cases I cannot help thinking that the pneumococcus vaccine was largely instrumental in bring about a favourable result.

Ellesmere, Salop.

LITERARY INTELLIGENCE.—Messrs. Henry Frowde and Hodder and Stoughton announce for early publication in a very long list of works the following:—1. A new revised fifth edition of Cunningham's well-known "Manual of Anatomy," Vol. I., edited by Professor Arthur Robinson, professor of anatomy at the University of Edinburgh. Cunningham's work is so well known that there is no intention on the part of the professor who has revised it to alter it in any way except in accordance with the international terminology and where it has appeared that new colour illustrations are desirable or the method of dissection has to some extent been altered to suit surgical needs. In these parts of the work a very thorough revision has been made, and it is hoped that the work will remain a worthy memorial of its author. 2. A large "Practitioners' Encyclopædia," by many authors, comprising medicine in all its branches. Nearly 1000 pages. In one volume. Edited by J Keogh Murphy, F.R.C.S. 3. A third volume of Thomson and Miles's "Surgery," dealing with "Operative Surgery." Pp. 500. With very numerous illustrations. This is in the press. It will be as small and compact as possible, but of very wide scope and very fully illustrated. 4. "A Text-book of Nursing, both Surgical and Medical," by E. W. Hey Groves and J. W. Fortescue-Brickdale, comprising anatomy and physiology as well as the methods of surgical and medical nursing, and designed to be complete in itself for nurses. Royal 8vo, pp. 388. 205 figures in the text. Companion to Despard's "Text-book of Massage." 5. "Surgery of the Rectum for Practitioners." By Sir F. C. Wallis. With about 130 illustrations. 6. "Gonococcal Infection." By Major C. E. Pollock, R.A.M.C., and Major Harrison. Pp. 222 7. "Surgery of the Skull and Brain." A large monograph by L. B. Rawling, F.R.C.S. Pp. 252, 96 figures. 8. "Salvarsan in Syphilis and Allied Diseases." By J. E. R. McDonagh, F.R.C.S. About pp. 175. 9. "Kidney Diseases." By W. P. Herringham. A large practical work.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

MEDICAL SECTION, WITH SECTIONS OF SURGERY AND ANÆSTHETICS.

Exophthalmic Goitre.

A JOINT meeting of these sections was held on Feb. 27th, Dr. FREDERICK TAYLOR, the President of the Medical Section, being in the chair.

The discussion on Dr. T. P. Dunhill's paper entitled, "Partial Thyroidectomy under Local Anæsthesia, with Special Reference to Exophthalmic Goitre," which is published in full in THE LANCET of Feb. 17th, p. 422, was renewed.

Dr. HECTOR MACKENZIE said that he proposed first to make a few observations on the paper itself, next to say something about his own experience of the disease and its treatment, and finally, to attempt to arrive at a right conclusion as to what kind of treatment is best and safest. Dr. Dunhill had said that he had operated upon 230 cases of exophthalmic goitre with only four deaths, a result as remarkable as it was gratifying from the surgical point of view. He wished Dr. Dunhill had entered into more detail about his cases. Dr. Dunhill mentioned four types of the disease, but he did not tell them how many of his cases belonged to each class, so that he (Dr. Mackenzie) could form no idea as to how many of the 230 cases were acceptable as genuine examples of exophthalmic goitre. This made it difficult to judge his results. Dr. Dunhill said that in cases of the first class, with local anæsthesia and expert operating, the danger was *nil*, but he had made little use of general anæsthesia, and, therefore, his experience did not help much in deciding the comparative risks attending general and local anæsthesia. Sir Victor Horsley had used general anæsthesia, and had had only one death. His own experience had taught him that roughly about 25 per cent. of the cases make a complete recovery, under general medical treatment another 25 per cent. recover, but bear signs of their former illness, about 25 per cent. live on as chronic invalids, and 25 per cent. died from the disease. At St. Thomas's Hospital until 1908 few cases had been operated upon; since then the cases so treated numbered 19. Six had died, 4 had improved markedly, 4 showed some improvement, 3 were unchanged, 2 relapsed and were readmitted. Two other cases were not followed. Of the 6 fatal cases, 2 died shortly after the operation, 1 two days after, 1 four days after, 1 eight days after, and 1 a year after, following operation for adenoma. Ligation of the vessels had been performed in some, and thyroidectomy in others. During the last year 7 or 8 had been operated upon; 1 had died, the others expressed themselves as better, none were cured. Where Dr. Dunhill's paper failed to convince was that the cases had not been followed long enough, and it was impossible to say if they would relapse again. His own belief was that there was a certain type of case in which it was dangerous to operate, whether under local or general anæsthesia. These were examples of what is called lymphatism. He thought operation should never be employed as a last resource. He had for a long time been feeling his way towards the adoption of operative treatment, but his path had been beset with obstacles. There had been a relatively large proportion of deaths, and the results in those who had survived had been disappointing. Were it not for the risk to life from thyroidectomy he would not hesitate to recommend it as the most rational and practical method of treatment. There was a good prospect of recovery under medical treatment in the milder forms of the disease, and there did not seem to be so much better prospect after operation as to warrant incurring the risk. In acute and severe cases he did not consider the operation justifiable.

Dr. ALBERT KOCHER (Berne) read a paper on the Surgical Treatment of Graves's Disease. He said:—

Mr. President and Gentlemen,—It was with great pleasure that I accepted the very kind invitation of the secretary of your society to take part in to-night's debate on Exophthalmic Goitre. There are but few diseases on which more

has been written in medical papers than Graves's disease. I am pleased to say that there is to-day nearly unanimity as to the pathogenesis of the disease being a functional trouble of the thyroid gland. The very different features, degrees, and course of the malady have, however, made it difficult up to the present to fix the exact functional change in the gland. Some pioneers, of whom I will only mention Sir Victor Horsley, Moebius, and Rehn, have, according to their own observations on different lines, described the disease as dysthyreosis or hyperthyreosis. The latter view, however, has gained ground very much by the results of surgical treatment, and my father, Theodor Kocher, who has been operating for 30 years on the thyroid gland in Graves's disease, is the main advocate of the theory of hyperthyroidism, basing his opinion on his extensive operative experience, of which he spoke at the meeting of the British Medical Association in 1910. The operations for Graves's disease in the surgical clinic at Berne up to date amount to 865, performed on 669 patients. With my father's kind permission I will speak of the whole of these cases, and not merely of my own, as we have observed and operated together on the great majority of these cases. As already mentioned by some of those who have spoken in the debate, it is difficult to class all the cases under one head. Allow me, therefore, to tell you in a few words how the different features of the disease have to be explained according to our present knowledge. (A) First, the different kinds of Graves's disease according to the condition of the thyroid gland itself (the following views are based on histological and chemical investigations on 200 glands of Graves's disease which will be published shortly in *Virchow's Archiv*). 1. The change in the thyroid gland in Graves's disease consists in the more rapid and more abundant absorption of the material stored in the gland follicles. There is a considerable difference in the quantity and quality of the stored material present in the gland at the time of the outbreak of the disease. 2. There is a marked hypertrophy of the epithelium. Both these changes are connected with a hypervascularisation of the gland. 3. If the disease is progressive all the stored-up material is sooner or later absorbed, according to its quantity and the rapidity of progress, and under further progression there is no more storing of material in the gland follicles, but the proliferation of the epithelium is still progressive all through the gland, and degenerative changes of the epithelium can take place together with formation and proliferation of lymphatic tissue. (B) The different kind of Graves's disease as to etiology. In the outbreak of the disease we distinguish neurogenic causes which act through the vascular nerves, and toxic causes of chemical and infectious nature, acting through the blood. They can be acute or chronic, and they can also be combined.

I will not take up your time any longer with this complicated matter; you may judge from these few remarks that a large, if not *the* largest, part of the different features of the disease lies in the thyroid gland itself. I wish, however, to draw your attention to one more point. There are a great many cases, especially combined with nodular goitre, which present a few symptoms of Graves's disease, and only occasionally (especially after iodine treatment) show exacerbation or pronounced hyperthyreosis. Since surgical treatment of the disease has become more common a great many surgeons operate, and all *these cases* are apt to be registered as Graves's disease cured by operation. This is not quite right; we should always make the following distinction. (1) Cases with symptoms of hyperthyroidism presenting only occasionally pronounced hyperthyreosis, which, however, does not last and is not progressive, being usually the consequence of unlimited iodine treatment; (2) cases of steadily progressive, and (3) of periodically progressive Graves's disease. The first also come from sudden or very rapid and abundant absorption of the thyroid secretion stored in the gland follicles (thyroid-diarrhœa, as my father calls it), but when the cause of the outbreak has passed by the gland does not undergo further change—the disease is not progressive. In the cases of the second and third type this takes place, and after a certain time of duration degenerative changes may come on, not only in the thyroid gland itself, but also in other glands with internal secretion such as the adrenals, pancreas, thymus, spleen, liver, ovaries. In other organs also permanent changes are established, such as fatty degeneration of the muscles, especially of the heart muscle, also of the kidneys and of the liver. We can, therefore, before looking upon the results, presume that in progressive Graves's disease it is *most important at what period* of the disease we operate, whilst in simple hyperthyroidism we do not risk so much in postponing operation.

Amongst our list of 669 cases, 130 were of simple hyperthyroidism, mostly combined with nodular goitre of nearly every size, some presenting no extraordinary difficulty during the operation; some, however, partly or totally intrathoracic, and being combined with hyperthyreosis, very vascular and technically very difficult operations. These cases have *all been entirely cured* of their symptoms of hyperthyreosis after the operation, with the exception of two, who died from post-operative pneumonia. In these cases we remove the cause of the disease with the goitre, and, more than that, we remove with the goitre the reservoir of the poison. Histological and chemical researches have shown that the goitre removed contains a large quantity of rather liquid colloid, in which an unusual amount of iodine is present. These cases are all suitable for operation if they are not complicated with other serious pathological changes in the lungs, heart, or kidneys. But it is advisable also to prepare these patients for operation by a short course of treatment, keeping away every toxic and nervous influence, because it is to be borne in mind for the operation itself that we have to deal with very sensitive people who are poisoned by toxins.

539 cases have been operated upon for steadily or periodically progressive Graves's disease. We are collecting the ultimate results, but with such a number they cannot be obtained as quickly as we should wish. We can at present give the ultimate results of 360 patients operated upon for progressive Graves's disease. 160 of these, 45 per cent., are radically cured, so that there is at the present time not one symptom of the disease left, and the function of the rest of the thyroid gland is normal. These cures last up to 25 years after the operation. The patients are leading a normal life, some working hard. Several lady patients have given birth to one or more healthy children since. Not all of these cases have been early ones; more than half were very severe and of long duration. The latter have been cured only after some time, during which several (up to 5) operations have been performed on the same patient. The early cases have been cured a short time after *one* operation. 149 cases, 41 per cent., show at the present moment, months or years after the operation, a few symptoms of the disease, but have been greatly benefited by the operation, inasmuch as patients of the working class, for instance, can earn their living without any difficulty. (*a*) Amongst these 149 cases there is first of all a considerable number in which a more extensive—that is to say, a second operation—would give complete recovery. Most of these patients, however, feel so well that they are unwilling to submit to any further operation. (*b*) In a small number of cases the only symptom still present is the exophthalmos, but they are not cases in which the bulb was most protruded before the operation, but cases in which the exophthalmos underwent no more change. They were sometimes combined with paresis of the bulbar muscles. I must mention here that among the 160 cases radically cured, a very large number have had an extremely marked degree of exophthalmos; in one instance the bulb came quite out one day and had to be replaced. At the present time the eyes are normal. (*c*) A further group of cases show symptoms which had been present before the operation and were the result of the toxic influence on some of the organs, due to the severity and long duration of the disease, such as chronic myocarditis, chronic nephritis, and some degenerative trouble in other glands, such as diabetes, but all symptoms of Graves's disease have disappeared. (*d*) Some patients still show symptoms of functional trouble of the thyroid gland. There is no more progressive disease, but the part of the gland left does not seem able to adapt itself to the various demands. We sometimes find symptoms of hyperthyroidism and sometimes of hypothyreosis. The gland seems to be in a labile state. The cause of this is that the progressive changes in the gland, during the Graves's disease, had gone so far that it had lost its power of storing material in the gland follicles, and the part of the gland left after operation was not able to regain this power.

However, all these 149 patients are cured of the great majority of the symptoms of Graves's disease and are able to lead a normal life. If we add this 41 per cent. to the 45 per cent. of complete cures, we can say that in 86 per cent.

the ultimate result of operative treatment has been satisfactory. In 28 cases, 8 per cent., the ultimate result cannot be called a satisfactory one. (*a*) Amongst these we find cases in which the operative treatment has not been carried on so far as to obtain a satisfactory result. Some of these patients object to further operation, not having been benefited by the first one. In some, however, the disease has gone so far, and also the shock of the first operation, sometimes only ligation of one or two arteries, has been such that a more extensive operation seems too risky, and is therefore abandoned. (*b*) The remaining cases of this group are those who have had recurrence of the disease. There are about 5 per cent. in all. In none, however, has the second attack been as severe as in the first instance—that is, before the operation. Amongst the cases registered as cured there is a number in which a second operation has cured the recurrent disease. Most of those also who show symptoms of recurrence might in a similar way be benefited by a further operation. But we have to bear in mind that partial removal (resection) of the remaining lobe of the gland in a recurrent case is extremely difficult, and therefore dangerous. It is true that in a few cases an excellent result has been obtained with it, but naturally the small part of the gland left has more difficulty in resuming its normal function. 22 patients, 6 per cent., have died since from other diseases. Only in a few instances does the former Graves's disease seem to be connected with the ultimate death. Five patients died very suddenly from what is called heartstroke, after a fright or over-exertion, or in the course of an otherwise not dangerous (mostly infectious) disease. In all these cases Graves's disease had been of very long standing, and had caused degenerative symptoms; however, after the operation the pure symptoms of Graves had disappeared. One case died from diabetes. Whether this is in connexion with the degenerative influence of the severe Graves's disease on the pancreas remains doubtful.

This leads to the question *which cases are suitable for operation?* If we could operate in all cases within a short time, say half a year after the outbreak of the disease, and the sooner the more acute the outbreak is, I dare say *all* might be *cured* by operation. A short rest with avoidance of all the things likely to cause progression of the disease, such as nervous strain and toxic influences, combined with more or less vegetarian diet and internal phosphorus preparations, is the proper preparation of these cases for operation. During this time a careful examination of the patient should be made, and this is *the chief point* to decide—whether an operation should be done or not in severe cases and of such long duration of the disease. Special attention must be paid to the heart, kidneys, liver, adrenals, pancreas, lymphatic organs (thymus, spleen, lymph glands), and to the blood. A constantly irregular pulse, a lasting notable amount of albuminuria, very frequent fatty stools, distinct and constant, not only alimentary, glycosuria, low blood pressure, marked status lymphaticus (especially the one without the otherwise characteristic lymphocytosis of the blood), a very high lymphocytosis of the blood, combined with very marked leucopenia, very slow coagulation of the blood—are facts that *forbid* an operation unless they can be brought to disappear under proper treatment during the time of preparation for the operation.

The operation itself consists either in the reduction of functional gland tissue by partial thyroidectomy or in the reduction of arterial supply by ligation of arteries. In early cases this will bring cure. In slightly enlarged, but very vascular glands, ligation of two or three arteries should be done; in larger glands hemi-thyroidectomy may be preferable. But one cannot fix any scheme, the most suitable operation for each case has to be decided upon individually. In severe cases of long duration the combined—that is to say, the consecutive use—of both operations is the method of choice. The ligation of the superior artery is best done from a small collar incision across the upper part of the lateral lobe, between omohyoid and sternocleido-mastoid, the upper pole of the gland is set free and the artery tied or cut between two ligatures. The effect seems to be better if ligation of the thyroidal veins is omitted. In partial thyroidectomy the larger lobe with the middle part and pyramidal process should be removed. This is done with Kocher's symmetrical collar incision across the middle of both lobes. After dividing the straight muscles above the entrance of the nerve branches, the gland is carefully detached under exact hæmostasis of all the numerous accessory veins passing from the capsule to the gland. It is an advantage if the superior and inferior artery can be tied soon. Special care is to be taken at the back, where the recurrent laryngeal nerve and the upper parathyroid gland are adjacent. The best plan is to leave a sheath of gland tissue behind. Next with regard to ligation of the inferior artery. The ligation of the inferior artery alone is as a rule a very difficult procedure, as it can only be done on the main branch, when the lateral lobe of the thyroid gland is lifted up. We do not therefore consider it the best method to be chosen, although it is the one lately chosen by most French surgeons. It has exceptionally to be done in cases where one lobe has been removed and the upper artery of the other tied. It is the same with the *partial removal or resection of the second lobe.* It is only exceptionally necessary and on account of the difficulty of hæmostasis not a safe procedure. The removal of one lobe and the partial removal of the other *in one operation* is a procedure which should not be undertaken. In early cases it is not necessary, in severe cases it is frequently the cause of death. We are sure that most of the cases lost after this operation could have been saved by consecutive operations performed at the necessary intervals.

All operation *can* and *should* be done under local anæsthesia. In early cases, where no symptoms of degeneration in the organs are present, general anæsthesia, ether and oxygen, can be given, but it has always two disadvantages: the recurrent laryngeal nerve cannot be spared with certainty, and the sickness after the operation, considering the slow coagulation of the blood, makes the healing slow, and has a bad general influence. The local anæsthesia is done by injections of ½ and 1 per cent. novocain solution with 2 drops of 1 per cent. adrenalin solution for 10 grammes of novocain. This is injected under the skin at the place of the incision, in the muscles where they are to be cut, and in the periglandular tissue, especially at the upper pole. It is important to calm the patient before the operation, not so much with drugs such as veronal, medinal, codein, and valerian, but more by mental influence. I can assure you that during the above mentioned preparatory rest cure in the house, which lasts from two to several weeks, we nearly always influence the patient so far that he is anxious to have the operation and fears it no more. After most operations, even if not the slightest irregularity, not to speak of complication, takes place, when no antiseptics and no general anæsthetic have been employed, the patient shows a very severe reaction; the more so, the more severe the case is. Rise of temperature and pulse-rate, irregularity of pulse, albuminuria, glycosuria, restlessness, sweating, and oppression are quite usual, and sometimes very alarming. We find this reaction sometimes even more severe after ligation than after partial removal. If antiseptics have been largely used, or if the wound has had to be packed with gauze, or general anæsthesia has been given, this reaction is much more severe. We have seen four times, in cases where we have had to give general anæsthesia because of the lack of self-control of the patient, this reaction go on for a period up to 24 hours, and ending in coma and death; and here the necropsy revealed fatty degeneration of the heart muscle, kidneys, and liver, with circumscribed necrosis, such as is found experimentally in the liver after chloroform death. Besides cases of death following the operation under general anæsthesia we lost 5 patients from pneumonia, 3 from nephritis (extensive fatty degeneration), 2 from embolism, and 4 who died, with the above-mentioned symptoms, very suddenly, and showed marked status lymphaticus, together with fatty degeneration at the necropsy. If you consider the cause of death in all these cases and compare with it what I said of the special attention that must be paid to the condition of the heart, liver, kidneys, adrenals, lymphatic organs, and blood, before operating, you may conclude that the majority of deaths could have been avoided. If we had omitted general anæsthetics in the four cases, if we had refused to operate on the three patients who had distinct signs of kidney degeneration before, and on the four patients who showed status lymphaticus in very marked degree, all these would have been spared, and our statistics showing 2·6 per cent. mortality from 865 operations would be only a little over 1 per cent.

Mr. President and Gentlemen, we come to the conclusion that early diagnosis of Graves's disease is *the* important task

of a medical man. If this is established an early operation should be performed by an experienced surgeon. After the operation treatment with rest, proper food, good air, especially mountain air, avoiding any nervous or toxic influence, will bring on radical cure in a fairly short time. Thus we shall not only avoid recurrence of the disease, but the patient will be spared from the toxic influence on his heart, kidneys, and liver, of which he will die sooner or later. The thyroid gland will resume its normal function, whilst, if the disease is progressive, it may come to such a point that the gland is no longer able to do so. In severe cases and in those of long duration a careful examination, according to our modern knowledge of the disease, must be made. Cases with distinct symptoms of functional degeneration cannot be operated upon without risk. Only surgeons who have great experience in the surgery of the neck, who are able to make complete hæmostasis, and who can guarantee complete asepsis, should operate in Graves's disease. A difference should be made between cases of goitre with symptoms of Graves's only, and the progressive full disease. The results of operative treatment in the first should not be published as results of operation in Graves's disease, without adding that they were rather cases of hyperthyroidism grafted on ordinary goitre.

Dr. DUDLEY BUXTON said that an important question was raised as to the relative advantages of local analgesia and general anæsthesia. He thought that Dr. Dunhill's objections to general anæsthesia were based on inadequate evidence, as he had had very small experience of general anæsthesia in these cases. It was important to know how the method was carried out, whether properly or improperly, and the results when quantities of anæsthetic were used which were adequate without being excessive. Local analgesia was certainly valuable, but whether it had the advantages claimed for it had yet to be shown. The after-sleep of general anæsthesia, he considered, was in its favour. He had employed chloroform for many years and quite agreed that it was more toxic than ether, but would only do harm when employed as a poison and not as an anæsthetic. If merely used to produce anæsthesia without overloading, no danger of post-operative poisoning from chloroform need be feared. A danger from asphyxia existed, but he had overcome that by giving oxygen *pari passu* with the chloroform, which he always administered by the dosimetric method. Nervous excitement and fright might be controlled by producing sleep before anæsthesia by a mixture of morphia, atropine, and scopolamine. Though he had employed chloroform he was ready to believe that the open ether method or venous infusion of ether were useful methods. In the latter, however, there was a danger of collapse when the unnatural stimulation of the ether passed off.

After Mr. H. J. PATERSON and Mr. JAMES BERRY had exhibited cases of Graves's disease which had been operated upon, the discussion was adjourned until March 5th.

PATHOLOGICAL SECTION.

A New Method of Mounting Museum Specimens.—Neuro-fibromatosis.—Multiple Embolic Aneurysms of the Pulmonary Artery.—Salvarsan Fever.

A MEETING of this section was held on Feb. 25th, Mr. S. G. SHATTOCK being in the chair.

Reference was made from the chair to the great loss which the section had recently sustained by the death of Lord Lister. A resolution, proposed by Mr. SHATTOCK and seconded by Dr. W. BULLOCH, expressing sympathy for the relatives was passed unanimously by the members standing. Subsequently the Chairman gave a brief *résumé* of the pathological researches which had led up to the late Lord Lister's work, and pointed out that aseptic surgery could only have been attained through antiseptic surgery.

Professor J. M. BEATTIE and Dr. ARTHUR HALL (Sheffield) showed a series of Mounted Specimens from the Pathological Department of the University of Sheffield to illustrate a new and inexpensive solution for the mounting of museum specimens. Specimens were fixed in the ordinary solutions (Kaiserling, Jores, or Pick), transferred to fresh methylated spirit until the colour was well developed, then directly to Frost's solution: sodium fluoride, 80 grammes; chloral hydrate, 80 grammes; potassium acetate, 160 grammes; cane sugar (Tate's cube), 3500 c.c.; saturated thymol water, 8000 c.c. In this they were permanently preserved. The advantages claimed for this method were: (1) It cost only one-tenth the amount of the glycerine solution; (2) it preserved more life-like colours; (3) the colour was not affected by exposure to sunlight or to extremes of hot or cold weather; and (4) the tissues continued to retain their power of taking ordinary histological stains.

Professor BEATTIE and Dr. HALL also showed specimens of Diffuse Neuro-fibromatosis. The patient was a girl aged 17 years. She had been curiously childish in manner, irritable, but easily pacified. She could not sit up in bed, showed general weakness and wasting, and was completely blind. There was marked swelling of both discs with dilated veins. She was almost completely deaf. Paralysis of the left sixth and seventh nerves occurred, and some difficulty was experienced in swallowing. There was marked wasting of the muscles of the hands. Tumours were present on arms, legs, and neck, evidently situated on the nerve trunks. There was one slight cutaneous nodule on the right side of the neck. The tumours were painless and not tender on handling. During her stay in hospital she became completely deaf, lost control of the sphincters, and (?) lost her taste. At the necropsy large numbers of tumours, varying in size from a pin's head to an orange, were found situated upon (1) the cranial nerves inside the skull; (2) the spinal nerves inside the dura mater and between the dura and bone; and (3) the peripheral nerves, particularly those of the brachial and lumbar plexuses. In the latter positions the largest tumours were found—one in the right lumbar plexus being of the size of an orange and having undergone marked degenerative changes. At the base of the brain the tumours were so closely packed together as to make it difficult to say to which cranial nerve each belonged. They had caused marked distortion of the medulla and pons. The olfactory nerves appeared to be alone unaffected. In the cord the tumours seemed more evident about the cervical and lumbar swellings and were very numerous in the cauda equina. Besides the actual tumours there was widespread irregular thickening of many nerve trunks. Microscopically the tumours consisted of simple fibrous tissue.

Professor BEATTIE and Dr. HALL also showed specimens from a case of Multiple Embolic Aneurysms of the Pulmonary Arteries. The patient, a man, aged 21 years, had thrombosis of the left leg in February, 1911, which seemed to recover completely in March. Shortly afterwards he had a shivering attack and blood-spitting. From this time onwards to his death in September he was more or less laid up with recurrent attacks of hæmoptysis, daily pyrexia, and occasional slight rigors. There were no loss of flesh, slight cough, and no pain. The only physical signs of disease in the chest were a small area of impaired resonance with harsh and jerky expiration, and occasional rhonchi situated in front, just below the right clavicle, and a smaller area about the second left interchondral space where fine crepitations were heard. Ultimately he was suddenly seized with profuse hæmoptysis and died within half an hour. At the necropsy both lungs were found to contain aneurysms of the pulmonary arterial branches. The largest was in the right upper lobe, extending from the anterior surface deeply towards the root of the lung. It corresponded in position with the site of the physical signs beneath the right clavicle, and measured 5 × 6 cm. across. The cavity was largely filled with organised laminated thrombus, near the centre of which a cavity containing recent liquid blood persisted. At the upper and deepest part this aneurysm had eroded into a bronchiole causing the fatal hæmoptysis. There were three or four smaller in size, some in the right and others in the left lung. Each was more or less completely filled with laminated organised thrombus.

Mr. EDWARD C. HORT and Dr. W. J. PENFOLD communicated a paper on Salvarsan Fever. Salvarsan fever was the latest addition to a large group of injection fevers. Other well-known members of this group were water fever, salt fever, sugar fever, ferment fever, protein fever, tissue fever, &c. In all of these the fever after injection had been attributed to the action of different pyrogenetic substances. Salvarsan fever, however, although at first looked upon as salt fever, had recently been attributed to gross bacterial infection of the solutions demonstrable before their sterilisation and injection. This theory was first advanced by Wechselmann and was later endorsed by McIntosh, Fildes, and Dearden as a result of independent observation. The theory

was mainly based on the discovery of large numbers of organisms in the solutions injected and on the experience that if saline made with pure water was used fever no longer occurred. The evidence, therefore, at first sight appeared to be complete. On testing it, however, by control experiments Mr. Hort and Dr. Penfold found that they could not produce fever by the injection of large numbers of dead organisms grown on water or on saline. They also found that injection of heated water or saline containing hardly any organisms may give rise to high fever owing to the presence of a heat-stable, filter-passing substance of small molecule. This substance might be of bacterial origin, but they had no absolute proof that this was so. If this body were present in sterile solutions containing salvarsan, fever followed injection; if salvarsan were injected in pure saline, fever did not follow injection. They found that water immediately after collection from the receiver of the ordinary closed metal still might be sterile and yet strongly pyrogenetic, and that water injected immediately after distillation in glass produced marked fall of temperature. This was also true of solutions of salt and salvarsan in this water. They suggested that the ordinary closed metal still when cooling aspirated organisms from the air through the joint with the worm, and that these were destroyed when the apparatus was again heated. It was possible that extraction of degradation products of bacterial protein then occurred, which would explain the pyrogenetic properties of sterile water. This water if allowed to stand in clean closed vessels became increasingly pyrogenetic, and injection of salt, salvarsan, and many other substances in such water was always followed by fever, which never occurred if pure water were the solvent. This toxic water was practically bacteria free, containing 40 organisms per c.c. If pure water, or saline made with it, were deliberately exposed to infection for some days, and were injected immediately after autoclaving, little or no fever resulted. If, however, an interval of days were allowed to elapse after autoclaving, and if injections were then made after a second heating, both the water and saline exhibited pyrogenetic properties. This also might be due to extraction of degradation products of bacterial protein. Mr. Hort and Dr. Penfold concluded therefore: (1) That there was no evidence to show that salvarsan fever was necessarily due to the injection of micro-organisms or of unbroken bacterial protein; (2) that the presence in the solutions of a heat-stable filtrable substance, which might be a degradation product of bacterial protein, was an important factor in the production of salvarsan fever; (3) that demonstration of the sterility of any watery solution of salvarsan was no guarantee that this pyrogenetic substance was not present; (4) that if water for the solutions was collected from the metal closed still autoclaving might be a distinct disadvantage; (5) that the only certain method of preventing salvarsan fever was (*a*) to use for the solutions only water that had been freshly distilled in glass and to inject immediately, or (*b*) if storage was desired the water must have been at once collected direct into sterile vessels, which were then hermetically sealed and autoclaved. Water treated in this way would not acquire pyrogenetic properties even after standing many weeks. Autoclaving after infection of the water had occurred was useless and probably dangerous.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

Exhibition of Cases.

A MEETING of this section was held on Feb. 23rd, Dr. G. A. SUTHERLAND, the President, being in the chair.

The following cases were shown:—

Dr. R. HUTCHISON: 1. Paralysis of the Muscles of the Neck (? Poliomyelitis) in a boy, aged 2½ years, who was admitted to the London Hospital on Oct. 28th, 1911. Ten days before admission he had had a feverish attack, and both ears discharged. Weakness of the neck had been noticed since. He was in hospital six weeks before that for pneumonia. On admission he was no more able to hold up his head than a newly born baby. Paralysis seemed to involve both sterno-mastoids, both trapezii, and retrocollic muscles, and was more marked on the left side. No other muscles were affected. Radiogram of the spine was negative. On Feb. 6th, 1912, there was imperfect reaction of degeneration in the trapezii and sterno-mastoids. The other muscles could not be satisfactorily tested. The paralysis is much less marked than when the patient first came under observation. 2. Hysterical Vomiting, Achylia, in a girl aged 10 years. About two years ago the patient's mother died suddenly, and vomiting set in immediately after this event, and continued in spite of treatment in two hospitals until she came under observation three months ago. She was then much emaciated (weight 1½ st.); the skin was dry, brown, and scaly. There was no other visceral disease. The bowels were somewhat loose. A test meal showed complete achylia. Under treatment by isolation, suggestion, and the use of hydrochloric acid and pepsin the vomiting had entirely ceased, but the nutrition had not much improved.

Dr. J. H. THURSFIELD: Green Teeth, subsequent to prolonged jaundice in the first weeks of life. The patient, a boy, had been jaundiced from birth, or possibly from the third day of life only, and during the first week of life he had passed very black stools, and had a purulent discharge from the navel. When seen at the age of 3 weeks the umbilicus was perfectly healthy; the liver and spleen were not enlarged, and the child, though small—6 lb. 5 oz.—seemed quite healthy. The jaundice was deep at this time and remained so for the next seven weeks, slowly disappearing. When it had gone he put on weight rapidly. He was not seen again until 9 months old, when he was brought for an attack of diarrhœa. Then the two lower central incisors were a vivid yellow tint, and have now become green. The tint varies considerably; it is occasionally quite bright, and at other times dull.

Dr. F. LANGMEAD: Anomalous Jaundice, with Enlargement of Liver and Spleen, with Bile-stained Teeth. Jaundice began between two and three weeks after birth, and persisted until the baby was 1 year and 3 months old. When first seen, when the child was 3 weeks old, the liver was definitely enlarged, and the spleen reached nearly to the umbilicus. The child's general condition was good. There was nothing to suggest syphilis. Grey powder was administered, and the liver and spleen subsided rapidly, and were not enlarged after about one month's treatment. The jaundice persisted and was accompanied by hæmorrhage from the bowel, the stomach, and beneath the skin. The first tooth erupted when the baby was 1 year old, and four were visible when the jaundice disappeared at 15 months. All were bright yellow in colour, and obviously pigmented by bile. Since then each tooth as it has erupted has proved to be jaundiced. The yellow colour began to change about three months ago, and now the colour has almost gone.

Dr. JAMES TAYLOR: Athetoid Movements in a girl, aged 5½ years. She was the seventh child; the first two died a few hours after birth; the third, fourth, fifth, and sixth are alive and well. The child was born at full term; she was born "feet first," and was black and blue at birth. She had never walked or even crept. At the age of 2 years the movements of the head, hands, and feet were noticed. Now she spoke badly (she had never spoken well), but her intelligence was fair. She had involuntary movements of the hands, also of the head; the legs were stiff. The reflexes were difficult to obtain on account of the rigidity, but the knee-jerks were present.

Dr. LEONARD GUTHRIE: Transposition of the Viscera in a girl aged 12 years. The heart was on the right side, the apex being in the sixth space 1 inch inside and below the right nipple. Hepatic dulness was absent on the right side, but could be made out on the left side from the level of the sixth rib downwards. The stomach resonance was well defined in the right hypochondriac region. The position of the colon was not ascertained.

Dr. J. A. TORRENS: Case of Unusual Cardiac Bruit in a girl aged 16 years. There was no history of rheumatism and no history of any cardiac disability at any time. She was a well-nourished and well-developed girl. There was no cyanosis or clubbing of the fingers. The heart was not enlarged to percussion, but the X rays showed a globular left ventricle of greater density than normal, suggesting some pure hypertrophy. There was a loud systolic murmur at the base, best heard over the aortic area, conducted up into the arteries of the neck, but audible over the entire thorax, back and front. The second sound was quite distinct, but there was no diastolic murmur.—The murmur was considered by some speakers to be due to a congenital lesion, and by others to an acquired aortic stenosis.

Dr. T. R. C. WHIPHAM: Arthritis of the Shoulder and Hip

(? Tuberculous) in a boy 14 years of age. When 3 years old he was held up by the arms, and after that his right shoulder "grew out" and the arm could not be raised above the horizontal level. Wasting of the shoulder muscles followed, but nothing further was noticed until nine months ago, when he started walking lame on the left leg. There was pain in the left hip and knee at first, but this had subsided, and the patient had never been prevented from doing his work as a house-boy. The radiogram showed absorption of the head of the humerus and displacement of the shaft under the tip of the coracoid process. The shoulder-joint was ankylosed. There was considerable wasting of the muscles around the hip-joint, the movements of which were very limited. The femur was shortened, due to absorption of the head of the bone. Von Pirquet's reaction was negative.—The case was considered as most probably one of tuberculous arthritis.

Dr. WHIPHAM: Proliferative Osteo-arthritis of the Hip in a youth. A year ago, when 17 years old, he began to experience pain in the left groin when walking. This was only present when the joint was exercised. He walked with a limp, and the left leg was ½ in. to ¾ in. shorter than its fellow. The muscles around the joint were wasted, and the trochanter was prominent. The movements of the joint were restricted, and creaking was present. The skiagram showed osteo-arthritic changes in the joint.—The case was considered by some to be of an infective nature, and the state of his teeth was commented upon as being a possible cause.

MEDICAL SOCIETY OF LONDON.

Exhibition of Pathological Specimens.

A MEETING of this society was held on Feb. 26th, Dr. J. MITCHELL BRUCE, the President, being in the chair.

The following pathological specimens were exhibited:—

Dr. FREDERICK LANGMEAD: Calcification of the Pericardium and Primary Carcinoma of the Liver in the same case.

Mr. C. M. PAGE: A large Obturator Hernia.

Dr. J. GRAHAM FORBES: (1) Spheroidal-celled Carcinoma of the Appendix in a boy of 10; (2) Tumours of the Cervical Sympathetic Ganglion; and (3) Fibro-myxoma of the Nasopharynx.

Dr. ALEXANDER PAINE and Dr. F. J. POYNTON: Experimental Appendicitis by general blood infection.

Dr. HERBERT FRENCH: (1) Melanotic Growth of the Liver; (2) Traumatic Aneurysm of the Heart; and (3) Malignant Disease of the Kidney, with continuous growth extending along the vena cava to the tricuspid valves.

Mr. HERBERT TILLEY: Larynx of a man, aged 72, whose right vocal cord was removed for epithelioma in September, 1896, and who died 13 years after from another growth on the left vocal cord.

Dr. C. E. LAKIN: (1) Infective Endocarditis in an infant of 7 weeks; (2) Infective Endocarditis in a case of congenital heart disease; (3) Malignant Disease of the Suprarenal Glands; and (4) Perinephric Tumour in a child of 4 months.

Dr. R. C. JEWESBURY: (1 and 2) Cysts of Spleen; (3) Separate Growths in Œsophagus and Stomach in the same case; and (4) Liver—for diagnosis.

Dr. J. P. HEDLEY: Specimen from Cæsarean Section.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

Exhibition of Specimens.—Pyocolpos.—Classification in Gynæcology.

A MEETING of this society was held on Feb. 16th, Dr. A. W. W. LEA, the President, being in the chair.

Professor H. BRIGGS showed: 1. Microphotograph and specimen of a Small Raised Ulcer, an early epithelioma, on the cervix of the procident uterus of a woman aged 63. On the procident cervix cancer is rare. 2. Two Ovarian Tumours, adenomata, solid, fused so completely that they formed one continuous ovoid 12 by 6 inches. The fusion must have occurred early; its cause was not yet explained. Ascites; no primary growth elsewhere; patient well after eight months. 3. A chain of Fibroids in each horn of a bicornuate uterus; the total bulk of the tumours was large and reached the umbilical level during life; both ovaries were apoplectic. There was a blood cyst in the great omentum; one broad ligament fibroid seemed to carry the corresponding ovary on its surface, and might have been classed as ovarian in origin except for its relation to the ovarian ligament and its own structure.

The PRESIDENT mentioned a case of Pyocolpos occurring in a girl aged 14½ years. This formed an abnormal swelling, reaching two inches above the pubes. The hymen was imperforate; per rectum it was obvious that the vagina was much distended. As the girl had suppuration in Bartholin's gland drainage was postponed until this healed. When the vaginal incision was made 12 ounces of muco-purulent fluid were evacuated. Infection had no doubt arisen from the bartholinitis. Recovery was uneventful.

Dr. A. DONALD showed the specimen and microscopic section from a case of Hæmorrhage from the Ovary. The clinical history was as follows. Married, aged 31; one child, born in March, 1909. Menstruation regular and health good. In November, 1911, sudden and severe collapse, with abdominal rigidity. Two days later retention of urine. On examination a mass of the size of a Jaffa orange was felt behind the uterus, rather on the left side. This condition persisted, and on Jan. 19th the abdomen was opened. Mass of blood-clot in pelvis, continuous with clot in left ovary. Specimen showed ovary size of Tangerine orange containing blood-clot, and there was also a separate blood-clot. Dr. W. F. Shaw, who furnished the pathological report, found cells which he regarded as lutein cells, but no certain evidence of ovarian pregnancy.

Dr. W. E. FOTHERGILL (Manchester) read a paper on Classification in Gynæcology, giving an account from the historical point of view of the various classifications of the diseases of women which had been used. It was shown that the anatomical arrangement now almost universally employed came into use about 40 years ago, while the first attempt to introduce the use of main groups based on pathology was made by Berry Hart in 1893. Dr. Fothergill considered that the anatomical system, while doubtless the best that could be used before the pathology of the diseases of women had been investigated, was not suited to modern needs. It interfered with the proper teaching and with the scientific description of the subject, and should be replaced, both in text-books and in courses of lectures, by a natural classification whose main divisions should be based on pathological features. Six main groups were suggested for use in such a system, as it was considered that the 10 or 11 divisions used by some authors were too numerous to be remembered easily by students.

EDINBURGH OBSTETRICAL SOCIETY.

Eclampsia.—Treatment of Contraction of the Pelvic Outlet.

A MEETING of this society was held on Feb. 14th, Dr. J. HAIG FERGUSON, the President, being in the chair.

Sir J. HALLIDAY CROOM communicated a paper on the Incidence of Eclampsia in the Edinburgh Royal Maternity Hospital, producing the statistics for a period of 22 years—first, with regard to its increase; secondly, with regard to its severity; thirdly, with regard to the mortality; and, lastly and specially, with regard to its seasonal incidence. He showed by numerous tables that there was a marked increase, especially during the last 13 years, and pointed out that it occurred less frequently in the country than in the town, and deduced the fact that the cause of the increase in cities was probably the alteration in the dietary. He further showed that the death-rate was distinctly diminishing, but that the severity remained unaltered. He explained this by a clearer knowledge of toxæmia and the patients being sent in earlier, and therefore more amenable to treatment. He also attributed the decreased mortality to improved methods of treatment which he discussed. With regard to the seasonal incidence, he compared the tables taken from many parts of Germany and from New York with his own, and found there was such a diversity of opinion on the subject, and the difference in the actual and relative months' occurrence so slight, that he was disposed to discard the seasonal influence in the causation of eclampsia, and endeavoured to prove that it was not a

question of seasons but the exposure of toxæmic patients to sudden changes of temperature at any time of the year, and he supported his opinion with numerous tables.—Dr. D. BERRY HART said that eclampsia was one of the diseases the more one read about it the less one knew, but there were theories. It must be remembered that there was a great deal of metabolism going on, and there was, perhaps, some disturbed chemistry varying in degree; also an accumulation of the toxin in the system until it reached a certain pitch, and perhaps aggravated by a change in the temperature. A very recent idea was that the woman might have eclampsia produced by a sudden change of temperature. The theory that the patient had previously diseased organs was difficult to prove.—Dr. JAMES RITCHIE referred to the fact that it might occur in a single pregnancy and not in any other pregnancy seemed to show clearly that it was due to something associated with that particular pregnancy. It must be explained by something in the uterus itself. He put forward a suggestion that it might be a micro-organism occurring in association with that particular pregnancy.—Dr. W. FORDYCE alluded to the statistics of the Edinburgh Maternity Hospital quoted by Sir Halliday Croom. The number of cases had increased and the death-rate had fallen. But the Maternity Hospital was not such a popular institution in 1889 as it was now, consequently only the desperate cases would be sent. Most men were now alive to the fact that the successful treatment of eclampsia could only be carried out in a hospital, and so there was an increased number of cases with a diminished death-rate.—Dr. G. KEPPIE PATERSON alluded to the possibility of some of the improvement in the death-rate being due to the general improvement in sanitation in the city. The mortality from infectious diseases had decreased in Edinburgh during the period under review. He had been an assistant many years ago in another city where there was a severe type of all infectious diseases—measles, diphtheria, and scarlet fever. While there within a year he saw several cases of albuminuria of pregnancy and of eclampsia. All the cases of albuminuria recognised and treated got well through the labour; all those where eclampsia set in during labour or where he had been called in for that condition died despite treatment, showing the severity of the type of eclampsia met with there. It was hardly fair to compare the statistics of other cities with those of Edinburgh; the climatic conditions were very different, and the state of sanitation in some continental cities was very deficient. The mortality from eclampsia in other cities might well be compared also with the death-rate in infectious diseases.—Dr. H. OLIPHANT NICHOLSON referred to the striking difference between the diet of town and country patients. If it was admitted that meat diet had anything to do with the disease, it was probable that there must be some defect in the proteid metabolism of the body; and that brought in the question whether some of the internal secretions, such as the thyroid, were functioning properly. In exophthalmic goitre, where there was an excess of thyroid secretion, one probably never got eclampsia. Persons with tubercle had also an excess of thyroid secretion, and so far as his experience went they never had eclampsia. The thyroid secretion had been shown to have some very important antitoxic effects.—Dr. J. LAMOND LACKIE mentioned two most interesting years in Paris. The climatic conditions were exactly the same, yet in the first year there was a very small number of eclamptic cases; in the second there were ten times the number. The cause was unexplainable. As regards the diet, he did not find that eclampsia was less frequent amongst the rich than amongst the poor; there was the same proportion of cases. The constitution of the patient and the climate seemed to be of no account at all. It seemed to him that diet had some effect, but how it acted he did not know.—The PRESIDENT referred to the statistics showing that in Edinburgh 1 in 35 of the cases was eclamptic, and 1 in 250 in other cities, but that was due to Edinburgh having such a large proportion of abnormal cases sent to the Maternity Hospital; other maternities had a far larger proportion of normal cases. He had experience of a home which admitted only primiparæ and for some time before confinement, and there no eclampsia had occurred. These patients had not a highly nitrogenous diet and were kept mostly in the house, and thus not exposed to climatic changes. A point of interest difficult to explain was that eclampsia occurred more frequently in plural births.—Sir HALLIDAY CROOM replied.

Dr. JAMES YOUNG read a paper on the Treatment of Contraction of the Pelvic Outlet, giving details of two cases—one treated by pubiotomy and the other by induction. He said: In this country contraction of the pelvic outlet has not received much attention. This is shown by the fact that in text-books and in discussions at medical societies, treatment of contracted pelves is almost always considered in terms of the diameters of the inlet. There are two types of contracted outlet: (1) where the condition is superimposed on a generally contracted or justo-minor state; and (2) where the contraction is limited to the outlet. This latter constitutes the funnel pelvis which is by far the more common of the two. It is probably due to an assimilation of the last lumbar and first sacral vertebræ. Where the distance between the tuberosities is reduced to 3½ inches, the posterior sagittal diameter should always be measured. This is done by placing a pencil across the outlet at the region of the bis-ischial diameter and then measuring between the centre of this and the tip of the sacrum. One centimetre subtracted from this gives the posterior sagittal diameter. The treatment of contracted outlet by induction is only approximately scientific, because there is no method, such as that available for brim contractions, of determining the relative sizes of the fœtal head and of the pelvis, and thus of deciding the most suitable time for interference. Pubiotomy possesses two great advantages—it enables the obstetrician to await the test of labour and it results in a permanent enlargement of the outlet. There is also a slight increase in the brim measurements in some cases, but this is too indefinite to increase the value of the operation for brim abnormalities. In the case of the outlet, on the other hand, it may transform a contracted into a normal pelvis with subsequent spontaneous deliveries. The disadvantage of pubiotomy (as also of Cæsarean section in favourable cases), as compared with induction, is that taken all over the maternal mortality of the former is 2 to 3 per cent., whilst in the latter it is practically *nil*. As the mother's interests must dominate the issue, induction is preferable in the average case. If pubiotomy or Cæsarean section is decided upon it must only be where there is expert skill at hand and where the woman has consented to the additional risks. First case: The patient was 28 years old, with a bis-ischial diameter of 3¼ inches and a posterior sagittal diameter of 2½ inches; other diameters were normal. The first labour was ended with craniotomy; the second labour was induced at the thirty-sixth week, and ended with difficulty by forceps, the child being born dead. Her third labour was ended by pubiotomy, with an easy birth and a living child of 8½ lb. weight. Convalescence good; a slight limp was present for two months. X ray photograph six weeks afterwards showed the union to be mainly fibrous. Second case: Bis-ischial diameter was 2¾ inches, and posterior sagittal diameter 3½ inches; other diameters normal. Induction of labour carried out at the thirty-seventh week by bougie; some delay of head in the pelvis. Child healthy, and 6 lb. in weight. Mother's recovery normal.—Sir HALLIDAY CROOM was against pubiotomy as an operation of choice. Pubiotomy should be the complement of forceps. Cæsarean section was better, and pubiotomy should only be done if Cæsarean section was refused.—Dr. LACKIE instanced a case of pubiotomy he had done for contraction of the brim. The operation was very simple and very easy; it only occupied 17 minutes till the child was delivered.—Dr. HART, Dr. FORDYCE, Dr. NICHOLSON, and the PRESIDENT made remarks on the paper, and Dr. YOUNG replied.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

Exhibition of Cases and Specimens.

A MEETING of this section was held on Feb. 2nd, Mr. R. H. WOODS, the President, being in the chair.

Dr. J. BOYD BARRETT exhibited photographs showing marked Asymmetry in the Face of a child. The lower jaw came over towards the right to the extent of two incisor teeth. There was neither wry-neck nor atrophy. Slight asymmetry was to be seen in the face of the mother. In reply to a question he said he could see no change in the

teeth corresponding to the change in the bones, the only difference being that the jaw had gone over to the extent of two incisor teeth, and, therefore, mastication had been somewhat difficult.

Dr. WALTER STEVENSON showed two cases of Congenital Dislocation of the Hip treated by Lorenz's Method. The first was in a little girl, aged 3, who had been in hospital for eight months. Skiagrams were exhibited showing the position when treatment commenced and at various periods during the progress of the case. The final X-ray photograph showed the acetabulum to be fairly well arched. The leg was still held a little in advance and abducted, but this was gradually improving. The patient could now get about very well. Treatment extended over 14 months. The second case was that of a boy aged 3 in whom the right hip was affected, which was more rarely met with. Treatment was continued for six months. Skiagrams were exhibited showing the progress of the treatment. Examination showed that the joint was now in good position.

Mr. W. S. HAUGHTON exhibited four skiagrams showing the progress of a case of Congenital Dislocation of the Hip, treated by Lorenz's method, in a child, aged 3 years, who was under treatment for more than 12 months. The first demonstrated the position of the bone at the commencement of treatment; the second the position when halfway through, with the thigh bone brought down to an angle below the horizontal, and the acetabulum more arched and bony; in the third a further extension of the arch of the acetabulum was to be seen; the fourth demonstrated the acetabulum in a still more forward position, with further ossification at the head of the femur. He said that the results demonstrated that Lorenz's method was safe and satisfactory, but as it had to be done with a considerable amount of strain it should be performed by those in the habit of dealing with bone cases.—The PRESIDENT said that the photographs showed clearly the process that took place in the growth of the acetabulum. It was clear that the method was scientific.—Mr. W. PEARSON also discussed the cases. Mr. STEVENSON, in reply, said that since April, 1910, he had come across seven cases, and in one case of double congenital dislocation the patient was 22 years of age. Very few cases were diagnosed before the patients commenced to walk, but the sooner treatment was undertaken the easier it would be to get the head of the femur into the acetabulum, and the bones were more likely to develop into better shape. Tenotomy was necessary in any cases that he had seen. The interval between the stages was guided by the X ray skiagrams.

Mr. W. I. DE C. WHEELER exhibited two cases operated on for Aneurysm in the region of the Cœliac Axis. One patient was back at work 15 months after operation; the second was operated on six months ago. Colt's instrument was used in both instances, a cage of 150 inches of gilded wire being introduced in the first, and a wisp of 105 inches in the second case.[1] The prominent symptoms before operation were intense pain in the back, marked epigastric pulsation, and digestive disturbances. A systolic murmur could easily be detected over the tumour. Mr. Wheeler considered that the pain in the back was more likely due to the stretching and heaving of the peritoneum of the posterior abdominal wall than to erosion of the vertebræ. This was borne out by a post-mortem examination on a third case. In each of the cases operated on by Mr. Wheeler the pulsation and the pain in the back became more violent for a few days after operation, then rapidly improved, the pain completely disappearing. Mr. Wheeler urged the necessity of rigid aseptic precautions, the technique for ordinary operative work being insufficient when a large quantity of metal was to be buried in the interior of a very diseased artery. These were the first cases shown in Dublin after operation for abdominal aneurysm.—The PRESIDENT, Mr. PEARSON, and Mr. A. J. MCA. BLAYNEY discussed the case.—Mr. WHEELER, in reply, agreed with Mr. Pearson that if fusiform aneurysm were wired death must follow. He would not like to say that his cases were cured, but in the first case a very fair result had been shown, while in the second there was less murmur, and all pain in the back had gone.

In the absence of Mr. W. TAYLOR, Mr. STOKES showed a case of Sacro-coccygeal Tumour, present at birth. When tapped a gap in the sacrum could be felt, through which the abdominal contents protruded. The fluid removed contained a large quantity of albumin and a trace of sugar.

Mr. BARRETT showed a child suffering from Talipes Calcaneo-valgus, one of the rarest forms of talipes, but the simplest form to treat.

Mr. WHEELER showed a case illustrative of the success of Operative Interference in cases of Hyperthyroidism. The patient had been treated for over three years by medicinal means without any improvement. She had marked tremors and tachycardia, her pulse-rate averaging 120. The blood count showed marked lymphocytosis and a leukæmia of the neutrophilic polymorphonuclear cells. She had lost weight and become intensely excitable and nervous. One lobe of the thyroid was removed. Free drainage after operation and administration of large quantities of saline per rectum were relied on to prevent a further poisonous dose of the secretion. None of the contraindications to thyroidectomy for Graves's disease were present. The symptoms were intensified for the first few days after operation, after which the patient made an uneventful recovery.

SECTION OF MEDICINE.

Insanity in Ireland.—Clinical Estimation of Blood Pressure.

A MEETING of this section was held on Feb. 9th.

Dr. W. R DAWSON read a paper on Insanity in Relation to some other Circumstances of Life in Ireland. In England and Wales mental affections were found to predominate together with pauperism in the rural districts, while alcoholism prevailed in the mining and manufacturing counties, there being no constant connexion between insanity and alcohol. In Ireland the distribution of insanity was found to follow a similar rule, though the differences were not so marked. The geographical incidence of insanity showed no relation to density of population, but corresponded to a considerable extent with that of pauperism, and to a less degree with the rateable value of land. It bore little, if any, relation to the emigration-rate, and none at all to the death-rate, either general or tuberculous. There seemed to be some slight correspondence between insanity and criminality as regarded their distribution in Ireland, but practically none between insanity and drunkenness; and in general it appeared that alcohol was of comparatively small importance as a cause of insanity in Ireland. The incidence of pauperism in that country bore little relation to that of poverty. Criminality prevailed in the large towns, as in England and Wales, while, on the contrary, drunkenness was in greater excess in the rural districts, in contra-distinction to conditions across the Channel.—The paper was discussed by Dr. T. G. MOORHEAD, Dr. H. C DRURY, and Sir W. J. THOMPSON (the Registrar-General)

Dr. G. E. NESBITT, in a paper on Clinical Estimations of Blood Pressure, said that instruments in use at present fell into two groups: 1. Those dependent on the application of a pad to an individual artery. These could not be regarded seriously as scientific instruments owing to the number of fallacies involved. 2. Those on which the pressure was estimated by an armlet surrounding the limb—e.g., the Riva-Rocci apparatus and its modifications. Though the possibilities of error with these instruments also were numerous, most of them could be guarded against, especially by the use of the auditory and visual methods introduced by Oliver. How much thickening and hardening of the vessels interfered with a correct reading of pressure was debatable. It might introduce a very serious fallacy. The estimation of diastolic pressure by methods based on the maximum of oscillation of the index was untrustworthy and practically impossible. Attention should also be paid to disturbing factors in the patient apart from disease—i.e., the fluctuation of pressure in connexion with the various functions and habits of life was considerable, amounting, according to some authors, to a daily variation of 100 mm. Hg. Errors of deduction must be guarded against. For example, low reading of blood pressure did not always mean freedom from vascular disease, and *vice versâ*. Though the method was often of service it must not supplant careful physical examination.—Professor THOMPSON said that many of the points referred to had been corroborated by experiments conducted in his own laboratory. In the hands of one who had not paid special attention to a particular

instrument the observation could not be of much use.—Dr. MOORHEAD said that he could not determine with his fingers whether blood pressure was high or not, and therefore, if an instrument could do this better than the finger it deserved its place in clinical work. He agreed that if arterial sclerosis co-existed in a material degree with a low blood pressure it proved that sclerosed vessels could not require a great compression force to collapse them. If they did, all cases of sclerosis should have a high blood pressure.—Dr. J. SPENCER SHEILL had observed that a rise in blood pressure was one of the earliest signs of the onset of eclampsia.—Dr. DAWSON said that in his experience there was invariably a rise in blood pressure in cases of melancholia and mental stupor, but that the fall that was supposed to take place in cases of mental excitement was not so constant.

LIVERPOOL MEDICAL INSTITUTION.—A meeting of this society was held on Feb. 15th, Dr. C. J. Macalister, Vice-President, being in the chair.—The following specimens were shown:—Mr. G. C. E. Simpson: (1) Lymphadenomatous Glands; and (2) a series of Appendices with Concretions.—Dr. Nathan Raw: (1) Primary Tuberculous Glands in the Neck with Extension to the Lungs; (2) Aneurysm of Aorta with rupture into the bronchus; (3) Tuberculosis of Body of the Uterus; (4) Tuberculosis of the Heart; and (5) Melanotic Sarcoma of the Dura Mater.—Mr. Arthur Evans: Gangrenous Ovarian Cyst.—Mr. W. Thelwall Thomas and Dr. Nuttall: (1) Chondro-sarcoma of the Breast; (2) Pylorus after Pylorectomy; (3) Mucocele of Appendix (two specimens); and (4) Cyst of Mesentery.—Mr. K. W. Monsarrat: (1) Sarcoma of the Thyroid; (2) Papilliferous Carcinoma of the Kidney; and (3) Fracture of the Skull and Brain Injury from a Revolver Bullet.—Dr. W. Blair Bell: (1) Exfoliation of Endometrium during Menstruation (lantern slides); (2) Bilateral Carcinomatous Sarcoma of the Ovary (lantern slides); and (3) Rhabdo-myosarcoma of the Uterus (lantern slides).—Mr. F. T. Paul discussed the specimens and gave instances of cases of pylorectomy similar to that shown by Mr. Thomas; also of mucoceles of the appendix. He did not think Mr. Monsarrat's case was one of sarcoma of the thyroid. He had seen many cases like it, and felt sure that the sarcomatous appearance was merely due to active proliferation of the normal cells. He agreed with Dr. Blair Bell that the bilateral solid tumours of the ovary shown by him could only be described as carcinomatous sarcomata.—Dr. R. E. Harcourt gave an account of the original tumours removed in the case described by Dr. Raw as "melanotic sarcoma of the dura mater." The histological structure of the primary growth, which originated in connexion with the optic nerve, was gliomatous in character.—Dr. Macalister spoke of the extreme rarity of tuberculosis of the heart.—Mr. R. E. Kelly read a note on the Pathology of Torsion of the Spermatic Cord, and showed an illustrative specimen. He stated that the usual form of so-called torsion of the testicle was not a complete twist of the whole organ with its covering of tunica vaginalis, but only torsion of the mesorchium. In these circumstances the latter structure, instead of consisting of a sessile attachment of the epididymis to the parietal layer of the tunica vaginalis, was found to remain in its primitive pedunculated condition; consequently the whole of the twist was limited to the pedicle inside this serous envelope. The specimen shown was obtained from a boy aged 19. The patient was lifting a heavy weight, when he felt something "give" in his groin, and he noticed for the first time a lump over the external abdominal ring. He stated that previously to the accident he had a perfectly descended testicle. Pain was never a prominent feature, and he did not come into the Royal Infirmary until six days later, when the lump, which proved to be a twisted testicle, was removed.—Mr. Thelwall Thomas mentioned two similar cases he had met with. In one of these frequent fainting attacks led to the discovery of the condition. He agreed that pain was not a marked symptom in most cases.—Mr. Simpson and Mr. Paul also recorded cases with which they had met.

OXFORD MEDICAL SOCIETY.—A meeting of this society was held on Feb. 16th at the Radcliffe Infirmary, Mr. Dodds-Parker, Vice-President, being in the chair.—Mr. E. C. Bevers showed a case of Facio-hypoglossal Anastomosis 19 months after operation. The details and difficulties of the operation were described in general. When at rest no paralysis could be detected, and a few movements could be made voluntarily. A good reaction was produced on faradaic stimulation.—Dr. Mallam showed a case of Ulcerative Colitis in a woman aged 35. Various drugs and a variety of medicaments used in lavage had no effect on the condition. Her weight varied for a long time just over 5 st. An organism isolated from the stools was not agglutinated by the blood serum, so vaccine-therapy was not tried. Appendicostomy was performed by Mr. Dodds-Parker. The patient weighed at the present time 6 st. 12½ lb., was much improved in general condition, and greatly so in the matter of her dysentery.—Mr. Dodds-Parker described the details of the operation.—Mr. Counsell related the history of a case of Liver Abscess in a young man. It began with slight gastric disturbance, pain and temperature developing into a typhoid condition, with frequent rigors. Widal's reaction to B. typhosus, B. paratyphosus (B), and B. coli was negative, and a blood culture was negative. An exploratory operation was performed because no improvement was being made, and because of a suspicious tenderness about the umbilicus, but no trace was found of gross lesion in any organ. The rigors ceased after the operation, but marked anæmia set in, and before death a slight pleurisy, which on puncture of the pleura yielded no fluid. The liver and spleen were continuously large, but no deformation of the former was noticed at any time. At the necropsy the liver was found to contain a large abscess in the centre of the right lobe and a smaller one in the left lobe. Streptococci were found in the pus and in the section of the wall of the abscess. The bowel was normal, and no site of infection was found.—Dr. Tyrrell Brooks read the notes of a case of Malignant Endocarditis which had been in the Radcliffe Infirmary. His symptoms at first were anæmia and a splenic enlargement; subsequently a murmur in the heart was found which altered slightly, and an aneurysm was discovered in the left iliac artery. A blood culture was made and a streptococcus found which could not be got to grow. A vaccine from another strain of streptococcus produced great improvement in the symptoms, and a considerable lessening of the anæmia. Death occurred after a few days of severe dyspnœa, and at the necropsy was found to be due to miliary tuberculosis—an ulcer in the thoracic duct from an old gland being found. The aortic valve had a plentiful crop of vegetations, the kidneys were of the flea-bitten type, and the spleen, which was very large, had an enormous infarct in it. Most of the organs showed miliary tubercles.

CHELSEA CLINICAL SOCIETY.—A meeting of this society was held on Feb. 20th, Dr. J. A. Mansell Moullin, the President, being in the chair.—Dr. T. B. Hyslop read a paper on the Intracranial Mechanism in Health and Disease. He contended that the nervous system was a mechanism or instrument which served as a transmitter, and not as a generator, of mechanical force. Quantitatively considered, the sum total of the intracranial contents, both in health and disease, was constant and invariable. Variations were possible only in the relative proportions of the component elements or contents. The deductions derived from the data of comparative anatomy, embryology, pathology, and experiment, as concerned with the structure and growth of the brain and skull, were discussed, and an experimental demonstration of the real nature of the intracranial mechanism, by which the balance of the intracranial contents was maintained, was given. The modes in which defects in the working of this mechanism impaired nutrition and function were discussed, and an account was given of the mechanism of the arterial, capillary, venous, and lymph systems in their several relations to disease. The sum total of the intracranial contents being thus constant, the variations in the relative proportions of these contents might be expressed (approximately) in mathematical formulæ. It became possible also to express in mathematical terms the conditions affecting the balance between internal and external relations and the various relationships between assimilation and dissimilation essential to the maintenance of intracranial equilibrium. In connexion with the structure and mechanism of nerve units, exception was taken to the "neuron theory," and evidence, as deduced from studies of the nerve elements in their several relationships, both phylogenetic and ontogenetic, as well as from anatomy, physiology, pathology, and experimentation, was given in support of a "trophon theory." The following points were submitted for discussion: 1. How far was the brain a transmitter, transformer, or generator of

energy? 2. Phylogenetically considered, was the medullary canal of man primarily alimentary in function; and, if so, did the change in function sufficiently account for the change in structure? 3. Was the sum total of the intracranial contents constant? and, if so, were they warranted in expressing conditions of "give and take" between the intracranial contents in health and disease in (approximate) mathematical formulæ? 4. What was the real nature of the cytoplasm (both nerve fibre and cell) as evidenced by variations in its structure and function? 5. Trophon *v.* neuron.—Dr. Leonard Hill and Dr. Claye Shaw took part in the discussion.

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held on Jan. 24th, Dr. A. W. Russell, the President, being in the chair.—Professor Munro Kerr read notes on: 1. A case of Intestinal Obstruction Complicating Pregnancy; operation at the seventh month without disturbing pregnancy. 2. A case of Advanced Extra-uterine Pregnancy in which the fœtus was free in the peritoneal cavity. In the first case the cause of the obstruction was a fibrous band in a large ventral hernia at the site of an old appendectomy scar. It was removed without disturbing pregnancy. In the second case the fœtus was free in the peritoneal cavity, where it must have developed. There was no trace of membranes.—Dr. Shannon read a paper on Some Observations on Concealed Accidental Hæmorrhage, with remarks on a case. The uterus showed small incomplete ruptures. There were several tears on the peritoneal surface, one of which, situated just above the bladder, was several inches in length. The mucous layer was intact. He was of opinion that the effusion of blood caused acute dilatation of the uterus and rupture followed. Death was caused by shock and not by the amount of blood lost. He performed Cæsarean section and hysterectomy, having previously ruptured the membranes to relieve the tension.—Mr. Duff read a paper on Successful Removal of a large Retro-peritoneal Sarcoma, with notes on the method of treatment. The tumour, which was of large size, was adherent to the greater curvature of the stomach and the transverse colon. About 7 inches of the peritoneal and the superficial layers of the colon were stripped in removing the tumour. This was covered with an omental graft. This method of using omental grafts he strongly recommended. There was a good recovery.—Fresh specimens were shown by the President, Professor Kerr, Dr. Stark, Dr. Marshall, Dr. Macfarlane, Dr. Ritchie, and Dr. Shannon.

Reviews and Notices of Books.

Handbuch der Hygiene. Herausgegeben von Professor Dr. M. RUBNER, Geh. Medizinalrat, Berlin; Prof. Dr. M. von GRUBER, Obermedizinalrat, München; und Prof. Dr. M. FICKER, Berlin. I. Band. Pp. 788. Price, paper, 27 marks; bound, 30 marks. II. Band, 2. Abteilung. *Wasser und Abwasser.* Pp. 410, with 111 illustrations and 3 coloured plates. Price, paper, 15 marks; halbfranz, 18 marks. Leipzig: S. Hirzel. 1911.

WE have recently received two volumes of this important work, which consists of contributions from numerous authors in the form of a series of articles on various branches of hygiene.

In Volume I., which relates to general hygiene, food, air, clothing, and soil, an introduction by Professor von Gruber supplies an interesting and philosophical discussion on the position which hygiene should occupy in relation to the well-being of the race considered from the widest point of view. Amongst some of the views which meet with criticism is the common one that by the prevention of disease a number of valueless lives are saved with a consequent depreciation of the average quality of the race. The view held by a certain school of sociologists, that "nurture" exerts only a minimum influence upon the nature of the individual, and that the efforts of hygiene towards the improvement of the body (soma) in contradistinction to the germ-plasm are almost valueless, is also criticised. In the opinion of the author hygiene has too long confined its attention to the welfare of the individual. He insists that the decisive criterion of the well-being of a race is the production of a numerous and healthy posterity, and that "hygiene" which fails to secure this has attained only a partial success. He considers, in fact, that the conscious regulation of propagation is a necessary link in the rational conduct of human affairs.

A short History of the Development of Hygiene from the earliest times is contributed by Professor Rubner. The lines along which this development has proceeded in different countries are traced, and a brief account of the growth of bacteriology and parasitology is given. The same author is responsible for a chapter on Metabolism and Energy Exchange, in which are discussed the chemical constitution of foodstuffs and their value for the purposes of nutrition and the supply of energy to the body. The methods employed in the investigation of problems of metabolism are clearly explained, and various questions, such as vegetarianism, minimum protein requirements, and the amount of food necessary for the proper maintenance of health, receive consideration.

Professor J. Mayrhofer contributes an article on Food and Food Adjuncts. In the section devoted to meat the subject of food poisoning is discussed, and useful references to work done on this subject are given. Mention is made also of the various methods used in preserving meat, eggs, and other foodstuffs. In this connexion it is interesting to find that Appert, who introduced the process of canning foods, attributed its preservative effect merely to the exclusion of air, a view which is still held by some packers at the present day. Milk and its preparations are also dealt with, and references are given to work which has been done on the enzymes of milk. In the section devoted to cereals the bleaching of flour receives attention. No mention is made of the addition to flour of the chemical substances euphemistically known in this country as "improvers," whence it may be hoped that they have not found their way into Germany. No account appears to be given of self-raising flour or of baking powders; although the practice of home-baking is universal in Germany the methods employed in the preparation and packing of baking-powder are inferior to those adopted in this country. Butter, margarine, and other foodstuffs, including condiments and stimulants, are also dealt with, and methods are given for detecting foreign substances with which they may have been adulterated.

Professor Lode contributes an article on the Atmosphere, in which the constituents of air are described, their physiological actions discussed, and, in the case of the more important constituents, methods are given for their estimation. Dust and other impurities receive attention, and the question of the toxic qualities of expired air is also fully dealt with. A useful section is devoted to the effect of compressed air on workers exposed to it, though it hardly brings out sufficiently the views which have been held concerning the relative advantages of gradual decompression and decompression by stages.

Professor Prausnitz contributes an article on the Effect of Soil upon Health, and gives an account of the methods that have been employed in researches upon soil and the results that have been obtained. Two articles by Professor Rubner describe the Hygiene of Warmth and Clothing. The correct fitting of boots is discussed in one of these articles as well as in an article by Professor Hueppe on Physical Exercises, in which the various systems of physical culture and their effect on health are considered. The volume concludes with an article by Professor Lode on Climate and its Effect on Health; an account of mountain sickness, the effect of climate on metabolism, and a discussion on acclimatisation are included in this section.

The subjects dealt with in the second of the volumes

(Vol. II., Band 2) are Water-supply, by Dr. O. Spitta; Sewage Disposal, by Dr. Schmidtmann, Dr. K. Thumm, and Dr. C. Reichle; and the Biology of Water and Sewage, by Dr. R. Kolkwitz. Germany for many years was far behind Great Britain in the provision of public water services and in precautions to secure purity of water. Much has been done in recent years, however, and in an introductory chapter on the History of Water-supply in Germany Dr. Spitta refers to the great stimulus given to the scientific study of the subject by the Hamburg cholera epidemic of 1892, which was fully investigated and described in the columns of THE LANCET,[1] the typhoid outbreak at Gelsenkirchen in 1901, and other epidemics which were traced to contaminated water. Fifty years ago there were only six important town water-supplies, whereas in 1903 the Imperial Board of Health was able to state that only 4 per cent. of towns with 15,000 inhabitants and over were still dependent on private wells.

An interesting chapter on the diseases due directly or indirectly to water is followed by detailed consideration of the various Natural Sources of Supply. Much space is given to the characteristics of ground water, a circumstance explained by the fact that about half the population and more than half the cities of Germany derive their supplies from this source. Dr. Spitta describes how the difficulties frequently arising from the presence of iron and manganese have been gradually overcome.

Under the head of Filtration, prominence is given to Kruse's view that the efficiency of the sand filter does not depend on the formation of a surface skin, but rather on the general sliming of the body of the filter. To obtain a satisfactory filtrate the maintenance of a constant pressure is regarded as most important, and for that reason mechanical filters are recommended only where there is no serious pollution of the raw water. The ozone method of sterilising water is favourably described. The practical difficulties which stand in the way of utilising ultra-violet rays are also made clear. The author is apparently unaware of Houston's work on the purifying effect of simple storage on Thames water. The classical memorandum of the Imperial Board of Health on the "Purification of Surface Water by Sand Filtration," is reproduced, and a short bibliography is given at the end of each chapter.

The section dealing with Sewage Disposal opens with an account of the development and present position of the sewage question. As in England, so in Germany, the state of the law in regard to the pollution of rivers is unsatisfactory. There is no central executive authority, but by judicious cöperation between the Imperial Health Council and the executives of the several States considerable progress has been made during the last decennium. In Prussia, pending the passage into law of a General Water Bill which has been in draft since 1907, the position is governed generally by an Order of 1901, which lays down the lines on which local authorities should take action for the prevention of water-borne disease, pollution of public supplies and nuisance to the public, and also for the protection of fisheries. A special account is given of the excellent work that has been done at the Prussian water and sewage experimental station under Dr. Schmidtmann. The standard in regard to sewage effluents has been considerably relaxed in recent years, and is now made to depend on local circumstances. Chapters follow on the composition of raw and filtered sewage, methods of domestic excrement disposal, and there is given a very complete summary of modern methods of sewage treatment, both "natural" and "artificial."

The common German practice of placing soil-pipes against inside walls, which we should consider objectionable in this country, is no doubt to be explained in large measure by the difference of climate. Disconnecting traps are rarely used and are not recommended. Drains are laid in cement only where they are subjected to much pressure. Joints are sometimes made with an asphalt mixture which is said to combine pliability with the merit of being gas-tight and water-tight. Of systems of sewerage a modified separate system appears to find greatest favour. Various forms of screens are figured and described, as is also Imhoff's ingenious sedimentation tank in use at Ems. Detailed reference is made to Stenernagel's experiments on sedimentation at Cologne, and also to Uhlfelder and Tillmans's investigations at Frankfurt a. Main. Dunbar's work on the processes underlying biological purification finds due recognition, but in the chapter on sludge disposal mention might have been made of Grossmann's experiments at Oldham.

As a whole, this section has been well prepared, and its value is considerably enhanced by the addition of a well-selected list of references to the literature of the subject.

[1] THE LANCET, July 7th (p. 46) and August 25th (p. 457), 1894.

The Control and Eradication of Tuberculosis. A Series of International Studies by Many Authors. Edited by HALLIDAY G. SUTHERLAND, M.D. Edin., Medical Officer to the St. Marylebone Anti-Tuberculosis Dispensary. Edinburgh and London: William Green and Sons. 1911. Pp. 451. Price 15*s*.

THIS volume contains a number of articles dealing with the control and prevention of tuberculosis. It is dedicated to Dr. R. W. Philip, and an open letter to him, and signed "Your Pupils among the Contributors," commences with the passage: "In asking you to accept this work on the Control and Eradication of Tuberculosis we do so not only as a tribute to the pioneer in this field of medicine, but also in the hope that these studies, bearing the impress of your teaching, and contributed by writers of many nations, may advance the movement in this and in other lands." These words sufficiently indicate the nature and scope of the work.

An interesting account of the principles and methods of the Edinburgh system is given by Dr. W. Leslie Lyall, assistant physician to the Royal Victoria Hospital for Consumption, Edinburgh. The fundamental principle of this scheme is that, not content with treating the individual patient who presents himself, the disease should be sought out in its haunts.[1] This is, of course, a sound contention, but it requires an elaborate organisation to carry it into effect. Dr. Lyall explains the details of such an organisation—namely: 1. The dispensary, where patients are advised as to treatment and instructed in such points as the disposal of sputum, necessity for windows being kept constantly open, sleeping arrangements, and segregation in so far as it can be carried out under his own domestic conditions. The duties of the nurses attached to the dispensary are duly described. 2. The sanatorium—the Royal Victoria Hospital—the buildings being in accordance with the latest and most modern style of sanatorium architecture. 3. Notification. 4. Hospital for advanced cases. 5. The farm colony, where patients are employed who have already been inmates of the hospital, but who still require a lengthened period of supervision before returning to ordinary life. This is a comprehensive and excellent plan, and if a similar scheme could be carried out in other large cities much would be accomplished in the direction of the prevention of tuberculosis.

Professor Béraneck, of Neuchâtel, contributes a short article on the theoretical and practical basis of tuberculin in treatment. The general conclusion of this paper is as follows. It is not possible to raise the resistance of organisms except by increasing the digestive functions of

[1] THE LANCET, July 31st, 1909, p. 284.

the leucocytes against the tubercle bacillus and its endotoxins. The tuberculins that are most likely to bring this about are those which contain the bacillary endotoxins in the form in which they are most easily assimilated by the leucocytes. Professor Béraneck describes the method of preparing a tuberculin which he maintains possesses the properties just mentioned.

Several chapters are devoted to the "anti-tuberculosis" movement in other countries, such as Canada, South Australia, the United States, Russia, Italy, and elsewhere. These chapters are of some interest, but we think it would have been well not to have confined the articles, as far as the United Kingdom is concerned, to the Edinburgh system and to the institutions founded on that system only. It would have been better if the work accomplished at the English hospitals and sanatoriums had also received notice.

Handbuch der Vergleichenden Physiologie. Herausgegeben von HANS WINTERSTEIN. 17. Lieferung. Band I.: *Physiologie der Körpersäfte.* Erste Hälfte. Bogen 11–20. Pp. 161–320. Price 5 marks.—18. Lieferung. Band II.: *Physiologie des Stoffwechsels.* Erste Hälfte. Bogen 72–98, nebst Titel und Inhalt. Pp. 1145–1562. Price 5 marks.—19. Lieferung. Band III.: *Physiologie des Energiewechsels, Physiologie des Formwechsels.* Erste Hälfte. Bogen 1 bis 10. Pp. 1–160. Price 5 marks. Jena: Gustav Fischer. 1911.

Dr. Fil. Bottazzi continues (17th Lieferung) his account of cytoplasm and tissue juices, and in doing so he gives an account of such matters as colloids, gels, and hydrogels, the work of Mann and Hardy in this country being fully acknowledged. The difficult physical problems that beset the investigator of such a subject as imbibition are expounded in a way which seems to give delight to the author, though the average reader will have to ponder over, and perhaps read a second time, the large number of physical facts which it has been contrived to tabulate. On p. 173 and subsequent pages the author shows concisely the application of these physical facts in the domain of biology. Crystallo-colloids and ions, adsorption, and hormones are next considered, but as to the hormones and how they act, "Wissen wir Nichts" (p. 211). The whole question of cell membranes is lucidly set forth in a comprehensive essay. The large part played by lipoids is fully discussed. A most interesting chapter is that devoted to the transformation of energy and the chemical processes that take place in living matter (pp. 263–290), full advantage being taken of the work of Benjamin Moore. The remainder of this "Lieferung" is devoted chiefly to "cell-juices." Dr. Bottazzi has done his work well, both in setting forth facts and in his acute criticisms on very difficult problems of cell physiology.

In the rather stout 18th "Lieferung," which contains the index for Vol. II., Professor Biedermann continues his elaborate exposition of the various methods and mechanisms by means of which animals take in, manipulate or digest, and then assimilate their food. The interesting mechanisms for the "prehension" of food by the chameleon and by various types of birds are first set forth, and the part played by the tongue is admirably described and depicted. A very full account is given of the salivary glands in animals, including the work of Pawlow, the chemical aspect of the question being also fully discussed. Then follows an account of the stomach in amphibia, reptiles, and birds (pp. 1178–1349), with a considerable number of illustrations from well-known authorities. The author writes with a full knowledge. Physiologists and zoologists alike would do well to consult and digest this elaborate chapter. The figure (No. 400) of the crop of a pigeon (after Marshall) is not so good as the classical one of John Hunter. All kinds of histological and chemical investigations are cited, so that we are almost bewildered with the array of facts. Even the ciliated and other parasites that occur in the alimentary tract of animals are fully described, while the whole question of digestion in carnivora, herbivora, and omnivora is set out with a minuteness of detail unsurpassed in any other treatise.

The movements of the intestine are dealt with in a similarly thorough manner from the amphibia upwards. Claude Bernard's figure of the pancreas in the dog (Fig. 456) is admirably reproduced, and so is his figure of the pancreas in the rabbit, but we miss his still more striking illustration of the appearance of chyle in the lacteals below the opening of the pancreatic duct. Nor does Professor Biedermann forget to introduce in his illustrations the latest results obtained by the Golgi and Cajal methods. We find what is to us a new name, "enterasen," exemplified by lipase (p. 1402 β). The literature alone occupies 27 pages. It is a slip that stomach appears as "stomac" (p. 1469), and taking the literature as a whole there are relatively very few English names.

R. du Bois-Reymond, a son of the famous physiologist of Berlin, has for many years devoted much attention to the "Physiology of Movement." Readers of this most interesting (19th) "Lieferung" will not be disappointed. Some may recollect Engelmann's masterly exposition and summary of protoplasmic, ciliary, and allied movements; the author, in his account, cites and extends the work of Engelmann. The illustration from Grützner on smooth muscle is rather poor (p. 28) and is lacking in proportion. On p. 32, should not "wic" be "wie"? Full use is made of Fredericq's interesting article on Autotomy in Richet's "Dictionary." Many pages are devoted to the physiology of motion in the various classes of animals, beginning with the mammal and ending with the medusæ, the sponges, and the protozoa, amongst the invertebrates. The work of Borditch on ciliary motion is not cited, while only one reference in the index of papers is made to the work of Ranvier. The special physiology of locomotion is next dealt with. The researches of Borelli, Pettigrew, Marey, Muybridge, Auschütz, Saville Kent, v. Uexküll, and many other investigators are agreeably set forth. Beginning with man and his movements on terra firma, the author deals next with those of birds—the media on or in which animals move forming the basis of his arrangement. A much better figure of the claw of the lion (after Owen) might have been found, and the same may be said of the illustration of periophthalmus (after Günther). In connexion with the movement of the foot of a snail or slug, there is no figure of the muscular waves which can be shown so convincingly by the kinematograph. The final pages deal with "movement in water." The author has condensed an immense amount of information into his article.

Applied Anatomy of the Lungs and Pleural Membranes, with Special Reference to the Apical Region of the Chest. By J. STUART DICKEY, M.D. Belf., B Ch. R U.I., Senior Demonstrator of Anatomy, the Queen's University of Belfast. With 50 figures. Belfast: Alexander Mayne and Boyd. 1911. Pp. 128. Price 5*s.* net.

THIS monograph is the 1910 Gold Medal Thesis for the degree of M.D. of Queen's University, Belfast, expanded for publication in book form. The thesis consists of a description of the regional anatomy of the lungs and pleural membranes, studied mainly with reference to the clinical importance which must of necessity be attached to a precise knowledge of the topography of the thoracic viscera. Special attention is given to the apex of the lung, and some discussion is introduced concerning the much-debated reason for the apical site of election of pulmonary tuberculosis. The fifty figures are admirable pieces of work,

and those especially which depict the relations of the apex and the thoracic operculum are to be commended for their accuracy. The text does not always fulfil the high expectations created by an examination of the figures, for in some places it consists of text-book quotations, which one feels to be unnecessary when so much material has been examined at first hand. Nor is the truth of all these quotations borne out by what the author has figured from his own dissections. For instance, in an actual section of the thorax, the lower end of the trachea is shown well to the right of the middle line, while Eicken is quoted as saying that it frequently deviates to the left, and the author, when giving reconstructed charts of the topography of the chest, places it in the middle line.

We feel that the author has done good and original work, and yet the stereotyped descriptions of the text-books, rather than the actual findings in the body, are at times the criteria on which he has formed his judgments. Perhaps it is a heresy to say so, but the feeling is irresistible that it were better not to consult the works of some 60 previous authors, when, as in this case, a sufficiency of material has been examined to warrant dogmatic statements, regardless of text-books, concerning the actual condition in the human body. One work the author does not quote, and this one we feel would have been more valuable than all those he has included; for there is perhaps no contribution to the study of the thoracic viscera which is based on more first-hand experience than the masterpiece of Francis Sibson, published in 1869.

Psychology of the Religious Life. By GEORGE MALCOLM STRATTON, Professor of Psychology in the University of California. London: George Allen and Co. 1911. Pp. 376. Price 10*s.* 6*d.*

THIS attempt to explain psychologically the religious life, and especially the vision of the ideal, is no effort to explain it away or to destroy its claim to man's belief. The discovery of the natural causes of religion does not imply that its ideal world has no reality except in man's thought; the dim and broken image of perfection may well be formed in sympathy and correspondence with a perfection that is most real. In his preface Professor Stratton points out that a psychological account of religion based merely upon answers received from individuals when questioned in regard to their religious experience must be but limited, as it will take no notice of the religious life of a wide variety of peoples who are by nature reticent or who are not easily reached for other reasons.

The author has escaped most of these difficulties by examining the prayer, the hymn, the myth, and the sacred prophecy of all nations—a method that furnishes to the psychologist the surest indications of different religions, as their adherents are, so to speak, taken off their guard, and examined without producing self-consciousness. In the religious life there is an inherent struggle. The presence of the Supremely Impressive makes the self and other men and all the common goods of life at once of value and contempt. Different people have a different sense of this discord. "The Greek pictured the world, somewhat as he built his temple, with a certain simple grace; while the Germanic mind, like the Gothic vault with its impenetrable shadows, saw the gloom and the evil close to what is fair; every person in varying degree reveals a peculiar feeling of the tension of the world." The greater part of the book deals with the various conflicts observed in religions—e.g., that between good and evil, those in regard to feeling and emotion, such as renunciation or acceptance of the world, appreciation or contempt of self; conflicts in regard to action, ardour or coolness towards ceremonial rites, and conflicts in regard to religious thought. On p. 241 Professor Stratton gives a striking example: "We often have in lynching an attempt in good faith to apply the abstract idea of justice in a definite situation; ..... but in its frenzy the mob catches no glimpse of the many sides of its conduct that are a wide departure [therefrom] and which really strengthen the hold of crime and injustice upon men." Homer describes the immortal gods "that exist for ever and never had beginning," and yet in contrast to this the actual narrative sets forth their birth and parentage in the human way. No story in Homer, however, could more flatly contradict the Church's higher abstract conception of what a divine character truly is than the account of God's anger with transgressors in the Old Testament. "His very anger testified to the bond between Him and men; indifference would have been a sign that the gulf was impassable." When we are impressed by the incongruity between such a representation and divine perfection it is "because we have lost sight of its many sides that are harmonious with even the highest ideal, and which give it value to one who is at once reverent and uncritical."

At the end of this most interesting work the central forces of religion are dealt with. "In the simple act of sight, hearing, or touch we always perceive more than our sense-impressions warrant. Human speech and laughter are in their bare reality a mere spatter of sound which we instantly amplify ..... into meaning. ..... The completion of the observed world by adding to it the great unobserved world, so real to the religious, is therefore no anomaly." The book is one that cannot be adequately reviewed in any short notice. Painstaking research is evident on every page, quotations from the Rig-Veda, the Zend-Avesta, and Confucius are compared with fragments of the Koran, while the practices of Iroquois, Algonquins, and various African tribes are mentioned when germane to the subject. But we have indicated that the work would be a valuable addition to the library of any serious student of the philosophy of religion.

Gewerbliche Vergiftungen; deren Vorkommen, Erscheinungen, und Verhütung. By Privat-dozent Dr. J. RAMBOUSEK. Leipzig: Veit and Co. 1911. Pp. 431. Price 13.50 marks.

FOR that increasing class of persons interested in industrial hygiene we know of no book so comprehensive, systematic, and rich in references as this work on Industrial Poisonings, their Causes, Symptoms, and Prevention.

The subject, if it is to be treated at all fully, requires a very wide knowledge, and Dr. Rambousek is qualified to deal with it. He is the medical officer attached to the Central Administrative Authority in Prague, having supervision over dangerous industries in Bohemia, and he is also a professor of hygiene in the University. He is, moreover, recognised as quite one of the ablest writers on industrial hygiene on the continent. We appreciate the careful planning of the work. It is divided into three parts: first, the sources of industrial poisoning, which involves detailed account of the risks incurred in processes for the extraction of metals and for the manufacture of the substances collectively spoken of as "chemicals"; second, a survey of the symptoms and pathology of the different kinds of industrial poisons—those having local effect especially on the skin, those acting on the blood, and those having specific effect on internal organs; and thirdly, preventive measures, including legislative enactments. Especially interesting are the sections dealing with the effects of petroleum, tar, benzene, and its nitro- and amido-derivatives, anilin and dinitro-benzol.

The value of the book to the English reader at all familiar

with the matter under review is the very complete account of the wide researches made on the continent, notably by K. B. Lehmann, of Würzburg; Lewin and Roth in Berlin; Wutzdorff and Leymann, of the Imperial Health Office; Glibert, of Brussels; Carozzi, of Milan; Teleky, of Vienna; and the late Dr. Chyzer, of Budapest. Reference to work done in this country appears to have been obtained mainly from papers contributed to international congresses or from abstracts of Home Office Blue-books and the like in German and Austrian papers specially devoted to industrial hygiene.

It is the fullest work of its kind known to us, and will be of great value to those who read German. It might well be translated.

The House Surgeon's Vade-mecum. By RUSSELL HOWARD, M.B., M.S. Lond., F.R.C.S. Eng., Surgeon to Poplar Hospital; Assistant Surgeon, London Hospital. Illustrated. London: Edward Arnold. 1911. Pp. 511. Price 7*s.* 6*d.* net.

AS the name suggests, this book is intended for the use of newly appointed house surgeons. It is likely to prove useful not only to all those who have to do with surgical work in the wards and out-patient department, but to those in practice who have not had the benefit of a resident post in a hospital. They will be able by its aid to acquaint themselves with the details of modern surgical practice. It is perhaps in the after-treatment of operation cases that the reader will derive the greatest benefit from its study, for it is the part of surgery which is the most difficult to acquire, and the most neglected in ordinary systematic works.

In the chapter on the sterilisation of the hands we are pleased to see that the author lays stress on the advisability of the surgeon keeping the hands free from all forms of contamination, not only when he is about to perform an operation, but at all times. He also rightly insists that too much reliance should not be placed on the use of gloves, for they are easily punctured or torn. The chapter on hernia deserves mention, for in it we find just those details that are generally missing from text-books, such as the exact method of performing taxis and of measuring a patient for a truss.

We have found much valuable information in the book and nothing to which exception can really be taken, and we feel sure that it should prove of much service to those for whom it is intended. It is well illustrated.

Précis des Maladies des Vieillards. Par ADRIEN PIC, avec la collaboration de S. BONNUMOUR. Paris: Octave Doin et Fils. 1912. Pp. 890. Price 10 francs.

THIS volume contains a full and excellent account of the various morbid processes as they affect individuals advanced in life. Some of the maladies described are peculiar to old age, others present phenomena rather different in character according to the period of life at which they occur.

The chapters on senile changes in the heart and vessels will naturally attract most attention, and the remarks on diagnosis and treatment are particularly worthy thereof. The changes that may be noted in the cardiac rhythm are well described, especially in reference to the slow pulse. The condition of artero-sclerosis is discussed at length and numerous useful hints are given as to prophylactic and active treatment.

A good account is given of pulmonary tuberculosis as it occurs in elderly persons. Practitioners in charge of workhouse infirmaries fully realise the frequency with which this affection is found in old age, and the old idea that tuberculosis of the lung was essentially a disease of young adults has had to be modified. Apart from arrested lesions, which have been shown to be so common in all adults, a progressive form of pulmonary tuberculosis is frequently found in elderly individuals. The disease, however, under such conditions, usually follows a slow course, and there is a strong tendency to fibrosis. In the volume now before us, full space is given for a discussion of this subject. The observations recorded are well worthy of study.

The greater part of the morbid conditions discussed are to be found described in various text-books of general medicine, or in monographs on particular diseases peculiar to advanced life; but there is much to be said for bringing such descriptions under one cover, where they will be easy for refeence.

Case Histories in Neurology: A Selection of Histories setting forth the Diagnosis, Treatment, and Post-mortem Findings in Nervous Disease. By E. W. TAYLOR, A.M., M.D., Instructor in Neurology, Harvard Medical School, &c. (The Case History Series.) Boston: W. M. Leonard. 1911. Pp. 305.

IT is difficult to know exactly what purpose is served by the compilation of 114 cases of the more frequent disorders of the nervous system. They are scarcely calculated to illustrate difficulties in diagnosis or to provide material for differential diagnosis, for in by far the greater number of them the diagnosis is very obvious. The remarks on treatment are somewhat scrappy; indeed, for many of the cases here reported no treatment was or could be availing. If a record of clinical and pathological data is to be of value it must be by the elaboration of detail; but many of the histories and examinations supplied by the author are too scanty to appeal to the neurologist. There are no clinical photographs or drawings to relieve the monotony of the record of cases which the reader has never seen; the book may possibly appeal to those who have actually seen the cases referred to, but otherwise it has little to recommend it. A few of the cases present points of some interest on which further information would have been welcome. Case No. 86, diagnosed as acute bulbar paralysis by the author, looks more like a case of pseudo-bulbar paralysis. Case No. 92 may conceivably have been one of subthalamic lesion, not of paralysis agitans. In any case, this is just a point on which more detailed differential diagnosis might have proved instructive. It is erroneous, we think, to state that "forced laughter is often very strikingly developed in certain lesions of the bulb."

LIBRARY TABLE.

Fortpflanzung, Vererbung, Rassenhygiene. Katalog der Gruppe Rassenhygiene der Internationalen Hygiene-Ausstellung 1911 in Dresden. Herausgegeben von Prof. Dr. MAX VON GRUBER und Priv.-Doz. Dr. ERNST RÜDIN. Mit 230 Abbildungen von M. VON GRUBER, nebst einem Bibliographischen Anhang von Dr. RUDOLF ALLERS. München: J. F. Lehmann. 1911. Pp. 178. Price 3 marks.—This is really a catalogue of the elaborate group of printed tables prepared to illustrate race hygiene as shown at the International Hygiene Exhibition held in Dresden in 1911. There are no less than 230 reproductions of these tables, with full descriptions, to illustrate such subjects as propagation of animals and plants, variation, selection, mutation, transmission of acquired peculiarities, laws of heredity in man, degenerations, racial hygiene, and neo-malthusianism, with several pages of bibliography. The preparation of the plates required the coöperation of many workers, while the Minister of State for Scholastic Education in Munich gave a substantial subvention in cash to carry out a most praiseworthy project, the first of its kind. The tables should prove particularly useful to zoologists, botanists, pathologists, and eugenists. We do not know whether they can be purchased in an enlarged form, but if they can be so obtained they would certainly be useful to lecturers. The work represents

a really enormous amount of labour, statistical and otherwise. It is a veritable mine of condensed facts graphically illustrated.

Kurzgefasste Chirurgische Operationslehre für Studierende und Aerzte. Von Dr. AD. OBERST, I. Assistent an der Chirurg. Klinik und Privat-dozent für Chirurgie an der Universität Freiburg i. Br. Mit 232 zum Teil farbigen Abbildungen. Berlin: S. Karger. 1911. Pp. 197. Price, paper, 6.20 marks; bound, 7 marks.—In this work the author does not confine himself to a description of the set operations most usually performed by students in a course of operative surgery, but includes also a number of other operations, such as those for hare-lip and for goitre. It is very suitable for the student of surgery, for it is written with great clearness, and the explanations of the various steps of the operations and the reasons for what is done are stated so that anyone can understand. There is no useless verbiage, yet the clearness of the explanation is not sacrificed to brevity. The numerous illustrations are for the most part excellent, though here and there an illustration is not so clear as might be wished—for instance, Fig. 165. It is a useful little book, and is evidently the work of one who is an experienced teacher as well as a skilled surgeon.

Applied Anatomy and Oral Surgery for Dental Students. By ROBERT H. IVY. London: W. B. Saunders Company. 1911. Pp. 280. Illustrated. Price 6*s.* 6*d.* net.—The author in the preface tells us that the book is not intended to replace larger works on anatomy and general and oral surgery, but rather to indicate to the student the subjects that require his particular attention. We think he has in a fair measure succeeded in his object. He realises that dental surgery is part of medicine, with the result that his teaching is sound. For example, we read that chronic abscesses in which there is necrosis at the end of the root of the tooth are rarely cured by so-called amputation of the root, and extraction of the tooth is the better course. The work, too, is thoroughly up-to-date, for we find under the heading of syphilis a brief but clear account of the Wassermann reaction. The illustrations are good, but we would suggest to the author, when any future edition is contemplated, that the more common forms of disease occurring in dental practice might with advantage be illustrated.

Materia Medica Step by Step. By ARTHUR W. NUNN. London: J. and A. Churchill. 1911. Pp. iv.-236. Price 3*s* 6*d.* net.—Of literature on materia medica there is an abundant supply, but there is room for a little book of this kind which is obviously intended for the beginner. The chemist's apprentice, with the raw drugs of the pharmacy at his command, and the medical student, with a cabinet of specimens, will find the lessons quite interesting and a pleasant introduction to a rather dreary, but necessary, subject. The student is taken over the ground in 31 steps, after each of which he must pause to answer a few suggestive questions. The author deals not only with the official drugs but also with the unofficial materia medica, of which a list appears in the syllabus of the minor examination of the Pharmaceutical Society of Great Britain.

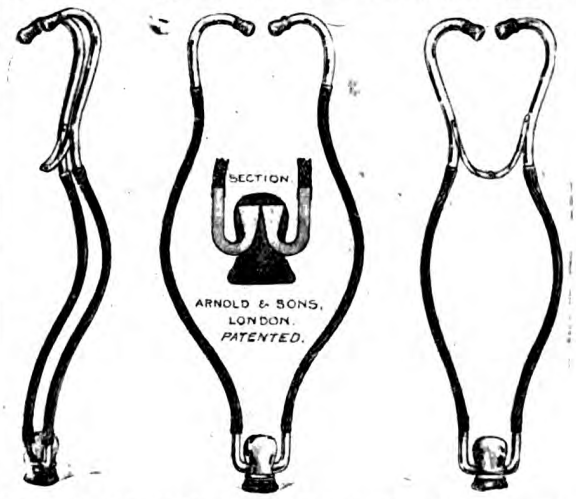
A Text-book of Inorganic Chemistry. By GEORGE SENTER, D.Sc. Lond., Ph.D. London: Methuen and Co., Limited. 1911. Pp. 583. Price 6*s.* 6*d.* net.—The plan of this book is in accordance with recent developments. The old text-book, which stopped short at certain fundamental laws and theories—such as the laws of the conservation of mass and energy, the laws of chemical combination, the atomic theory, molecules, the periodic classification—is not complete for the modern student in view of the enormous importance which the developments of physical chemistry have gained in regard to the interpretation of chemical phenomena. Dr. Senter gives us a modern text-book in which the meaning and significance of new principles are carefully and methodically presented, while he introduces for the reader's consideration and study the subjects of chemical equilibrium, the determination of molecular weights in solution, electrolysis, and electrolytic dissociation—those branches of chemical theory, in short, which constitute new principles. He retains the method which, surely, must ever be right—viz., that of presenting first the simple facts upon which laws and theories are based. Dr. Senter writes from an obviously intimate acquaintance with the needs of the student of chemistry and in a way calculated to develop the reasoning processes of the reader.

Handbook of Electro-therapeutics. By WILLIAM JAMES DUGAN, M.D.—In our review of this book in THE LANCET of Jan. 6th, 1912, p. 30, we gave the name of the publishers of the book only as Messrs. F. A Davis Co., Philadelphia. We should have added the name of the London agent, Mr. Stanley Phillips, 23, Creighton-road, Queen's Park, London, N.W., who supplies all books published by Messrs. F. A. Davis.

New Inventions.

A NEW PHONOPHORE STETHOSCOPE.

Messrs. Arnold and Sons, of Giltspur-street, London, E.C., have invented and patented a new phonophore stethoscope for which they claim certain advantages over the ordinary stethoscope. The new phonophore is provided with two conducting tubes from the bell instead of one, as in the old form of that instrument. The result is that the sound listened to is conducted separately and equally to the two ears, and it is heard more loudly and distinctly. It is claimed that this



instrument is useful in cases with doubtful cardiac murmurs, and in those in which emphysematous lung renders the heart sounds feeble and indistinct; and further, that normal breath sounds are heard more loudly than with the ordinary stethoscope. We have tested the instrument, and find that it is more convenient than the old form of phonophore, and that it conducts sounds well. The prices are the same as were those of the older variety, ranging from 6*s.* 6*d.* to 13*s.* 6*d.*

BRITISH ASSOCIATION.—The president of the next meeting of the British Association for the Advancement of Science at Dundee will be Professor E. A. Schäfer, M.D. Among the presidents of sections will be Professor G. Elliot Smith, Anthropology; Dr. Leonard Hill, Physiology; and Professor A. Senier, M.D., Chemistry. Dr. Arthur Keith will deliver one of the evening discourses. The meeting will begin on Sept. 4th.

THE LANCET.

LONDON: SATURDAY, MARCH 2, 1912.

The National Insurance Act.

ALTHOUGH there has been no abatement of genuine interest in the National Insurance Act within the ranks of the profession, the past week has been one of comparative quiet in the medical world so far as outward signs go. The Representative Meeting of the British Medical Association on Feb. 20th–22nd arrived at conclusions which have brought it home to all that there is a pressing need for a steadfast attitude. The state of comparative calm in which we now are suggests very strongly that the practical compromise reached by the opposing parties in the governing body of the Association has been approved by many of their constituencies, and that some basis of united action has at last been hammered out. This view depends, of course, upon the assumption that the Council of the Association, in whose hands all executive power is vested, intends to carry into effect the instructions which it has now received. The policy set out in the leading resolution of the Representative Body, and unanimously agreed upon by the delegates, seems to stand midway between the courses advocated by extremists on either side, and has met with little adverse criticism. But while for the present the tide of comment has receded, it is clear that the National Medical Union is not content with a situation that still has its deep anxieties. A moderate policy which can weld conflicting medical interests without estranging public sympathy may carry the day for the medical profession, but it is idle to suppose that the battle is won because peace may be restored within the ranks of the British Medical Association. In the long and arduous struggle which is still ahead the advice and support of the great corporations should prove of real value.

The demand that the minimum requirements of the medical profession should be guaranteed in the Regulations, with a view to their ratification by Parliament, and the intimation that failing this the medical profession will stand aside from the Act, seem together to strike a mean between the wholly *non possumus* attitude and the dangerous plan of continuing flaccid negotiations. When the Act, in a form which all men saw to lead straight to numerous difficulties, became law at the close of last year, the split in the medical profession seemed for the moment beyond repair—a party which wished to work the Act was straightly opposed to one which would have none of it, and the political newspapers worked hard to widen the breach. It was then that we made the suggestion that the way out of the *impasse* was for the medical profession to concentrate attention upon the Regulations, and only to refuse medical service if these proved to be unsatisfactory. This proposal, we considered, would avoid the probability of disastrous local bargaining, while avoiding also the attitude of complete summary refusal. Recent events have shown that this policy is acceptable to many medical men of divergent opinions as a workable basis of union, and if the constituencies of the British Medical Association can also bring themselves to accept the compromise arrived at by their Representatives, and to stand by it while the crisis lasts, the future can be regarded as brighter. Union within our body must exact all the recognition of our rights which it is in the scope of the Commissioners to grant; and if their powers fall short of what some believe of them, our solidarity will lead the Government to amend the Act, lest a brave scheme for improving the nation's health should fail miserably of its main object.

The Present Position of Salvarsan.

ON the first introduction of a new drug it is by no means easy to express a decided opinion as to its merits, especially when the disease for which it is employed is liable to reappear many months and years after apparently it has been cured. Of all diseases with which we are acquainted syphilis is probably the one about which it is most difficult to be certain that a permanent cure has been effected; for after intervals which may often be measured by years some manifestation may appear showing clearly that the virus has been latent in the body during the lengthy interval. Therefore when a new remedy is brought forward as more capable of effecting a complete and permanent cure of syphilis than was possible or at least easy by any other method, it is only natural that some of those who had many years' experience in the treatment of the disease should look askance at a remedy for which so great a claim was made; for by means of mercury judiciously, perseveringly, and thoroughly administered results of the very greatest value have been obtained. It is difficult to forsake a tried remedy for a new drug. Now sufficient time has elapsed since the introduction of salvarsan for us to form some idea as to its value and its risks; it is, however, not yet possible to make any dogmatic statement as to the position which the remedy will hold in the future—whether in, say, ten years' time it will be widely used or whether it will have lost much of its present popularity. That salvarsan has a great power against the treponema pallidum is beyond dispute, but the occurrence of a number of fatal cases has shown that it is by no means free from danger; we are, perhaps, in a position to inquire whether these deaths are a necessary accompaniment of the administration of the drug or whether they, or most of them, might have been avoided by greater attention to the method and details of administration.

It must not be forgotten that salvarsan was not a natural substance employed empirically, but a substance obtained as the result of a long series of experiments conducted on the most modern scientific lines. The problem

which EHRLICH set himself was to find a substance which should prove inimical to the treponema, while at the same time it should damage to the least possible extent the normal tissues of the body. His object was to obtain a substance which could destroy completely all the organisms of the disease with one injection, and yet should not harm the host. Whether salvarsan is capable of effecting this cannot yet be said to be proved, but it is at least certain that it has a very great influence on the treponema and that the manifestations of the disease respond as a rule very readily to it. The amount of evidence both as to the merits and the risks of the drug are now numerous, and a reference to the indexes of THE LANCET for last year will show that we have devoted a large space to papers on this subject, and we have done so because we have felt the great importance of the matter. For a final judgment we must wait for some years, but it is at least possible at present from the materials in our possession to express an opinion on the value and risks of the drug. All those who have had much experience of the use of salvarsan are agreed that it is capable of causing the rapid disappearance of syphilitic manifestations; it is true that some lesions seem to be more amenable to its influence than others, but in nearly all cases the action is rapid and effective. In fact, most observers are of opinion that it is more rapid and more effective than is the action of its main competitor mercury. It is true that there are some clinicians who decline to acknowledge that the efficacy of the drug is great, but they are comparatively few in number. The point of the controversy now is the question of the risk attendant on the use of the drug. At first the risk was said to be very small, but at that time it was employed by but a few surgeons, and it was administered with the greatest care, while since the use of salvarsan has spread widely it has been employed much more freely; and it must not be forgotten that the dose has been increased, while in many cases it has been thought necessary to administer a second dose.

That the drug can cause death is certain, and by now a large number of fatal cases have been published. In some of the earlier deaths the fatal result appeared to be due in part at least to the fact that the drug had been administered to patients who were almost moribund, but that explanation cannot be allowed in most of the more recent deaths. In the last issue of THE LANCET we published a letter in which are collected together a number of recently reported fatal cases after the injection of salvarsan, and the list is sufficient to make us consider with great care the risks of the drug. As to some of the cases it is possible to suggest the cause of the fatal result. It appears that in two of the cases mentioned the full dose of 0·6 gramme was repeated after a very brief interval; in one case the interval was only three days and in the other it was a week. Now it has not yet been shown that there is any anaphylaxis with salvarsan, but whether there be or not, it is, to say the least, very unwise to inject so large a quantity of the drug as 1·2 grammes within three days or even a week. It may be answered that it has been done with impunity, but such a dose is extremely large, and the fatal result is not strange. This is pointed out in our columns this week by Dr. G. S. STOPFORD-TAYLOR and Dr. R. W. MACKENNA. It may be necessary to repeat the dose in some cases, but it is certainly advisable that an interval of greater length than a week should be allowed to elapse between the two injections. In some of the fatal cases in which only a single dose has been given the symptoms have pointed to the presence of a meningitis, and they have arisen within a few days of the injection, and in others nephritis has occurred. These are evidently the direct effects of the drug. It is of interest in such fatalities to know whether the solution was filtered before it was injected intravenously, for it is easy to see that minute solid particles of the drug might have a harmful effect that would not be produced by a solution. It is very desirable that in reports of cases where very severe symptoms or a fatal result have occurred that the fullest particulars should be given of the mode of administration, especially as so many different methods are now employed. There is a further point that is worthy of consideration, and that is the relative frequency of fatalities. By now the drug has probably been given in one way or another in more than 100,000 cases, but we have no evidence as to the proportion of fatal results, though a few surgeons have published the statistics of their own cases. The present position of the matter is that salvarsan has been proved to be a powerful antisyphilitic agent, that in a large proportion of the cases in which it has been given it has produced no harmful symptoms, but that in a small number of cases severe symptoms have appeared, and in some cases a fatal result has followed. There is evidence to show that in some of these fatal cases at least the death has been due to the too early repetition of the dose, and in other cases possibly some error in the mode of administration has been committed. It is clear that the drug has a very definite value, but it is equally clear that its administration needs the greatest care. It is not improbable that a certain amount of selection of cases will be necessary if the best results are to be obtained, but at present it is hardly possible to say what cases should be excluded from the treatment, though there is some reason to think that nephritis is a contra-indication to the administration.

Annotations.

"Ne quid nimis."

PRESERVATIVES IN MILK AND CREAM.

AS was foreshadowed in an annotation in THE LANCET of Feb. 17th, the Local Government Board, in the exercise of its powers under the Public Health Acts, has drafted regulations prohibiting the use of preservatives in milk and defining the conditions under which preservatives may be used in cream. The regulations are far-reaching in character and apply to all milk and cream sold for human consumption in this country whether produced here or imported from abroad. The Board appears to have been guided in the case of milk by the recommendations of the Departmental Committee, which in 1901 recommended that the addition of preservatives to milk should be made an offence, but in the case of cream the Board has not followed precisely the direction indicated in the Committee's report. The Committee recommended that only boron preservatives should be allowed in cream in an amount not exceeding 0·25 per cent., and as will be shown presently, the draft regulations

as they apply to cream, are more stringent in their requirements. The use of preservatives in milk is prohibited in the following unequivocal terms of Article III.: "1. No person shall add, or order or permit any other person to add, any preservative substance to milk intended for sale for human consumption. 2. No person shall sell, or expose or offer for sale, or have in his possession for the purpose of sale any milk to which any preservative substance has been added in contravention of subdivision (1) of this article." The expression "milk" includes separated, skimmed, condensed, and dried milk, but as the traffic in condensed milk would be seriously impeded if the use of sugar were disallowed it is provided that "neither cane nor beet sugar shall be regarded as a preservative or a thickening substance." It will be remembered that in a report to the Local Government Board in September last year Dr. F. J. H. Coutts [1] showed that there were serious drawbacks to the use, except for temporary purposes, of full-cream sweetened condensed milk as an infants' food, the most objectionable feature being the excess of sugar in relation to other food elements, but the Board in drafting its regulations no doubt deemed it inexpedient to prohibit the sale of a product which, in exceptional cases, may be a useful article of diet. It is the function of educational and not legislative measures to teach those who have the care of the young that although a certain article of food may on occasion be useful, it should not necessarily be used habitually. In the same report Dr. Coutts suggested that the use of condensed skim milk for infant feeding should be prevented, as it implied a slow process of partial starvation, but the Board has not given effect to this suggestion since it would hardly be germane to the principal purpose of the regulations. The restriction placed on the use of preservatives in cream is as follows: "1. No person shall add, or order or permit any other person to add, (*a*) any thickening substance to cream or preserved cream; (*b*) any preservative substance to cream containing less than 40 per cent. by weight of milk fat; (*c*) to cream containing 40 per cent. or more by weight of milk fat any preservative substance other than (i.) boric acid, borax, or a mixture of these preservative substances, or (ii.) hydrogen peroxide, in amount not exceeding 0·1 per cent. by weight, in any case in which the cream is intended for sale for human consumption. 2. No person shall sell, or expose or offer for sale, or have in his possession for the purpose of sale, any cream to which any thickening substance or any preservative substance has been added in contravention of the provisions of subdivision (1) of this article." Dealers in cream, preserved in a manner which does not contravene the above regulation, will be required, by means of labels on the receptacles, to declare that the cream is preserved and to state the name of the preservative. In this matter the regulations are precise, laying down in a schedule the size of the label, which varies according to the capacity of the receptacle, and prohibiting the attachment to any receptacle of a label bearing a trade description which would be likely to mislead a purchaser as to the utility of the preservative substance. In tea shops and other refreshment rooms the cream jugs will not be required to be labelled if in each room a conspicuous notice is affixed indicating that the cream supplied is preserved cream, or if a statement to that effect is printed on the bills of fare. The penalties for offences against the regulations will be those for which provision is made by Subsection (3) of Section 1 of the Public Health Act, 1896, but before the local authority institutes proceedings against any person they will be required to afford him an opportunity of explaining the circumstances in which any irregularity may have occurred. With the exception of the provision relating to the labelling of preserved cream, which takes effect on Jan. 1st, 1913, the regulations will come into force on June 1st next, at the beginning of the warm season.

THE STORY OF ANCIENT MEDICINE REVEALED BY GREEK INSCRIPTIONS.

Professor Oehler, of Vienna, has been summarising the Greek lapidary records having reference to medical men in antiquity, with interesting results. The earliest record of the kind as yet copied into the corpus of Greek inscriptions refers to a person named Aineios, an Athenian, who lived in Athens about the end of the sixth century B.C. The most recent text of this category known concerns a medical man named Petros, a citizen of Claudiopolis, and is of the date of 511 A.D. Taking the collection of these inscriptions as a whole, it is found that the term used in them for a physician varies considerably. Instead of the common expression, *ἰατρὸς*, the following variants appear: At Seleucia, in Syria, we find *εἰατρος*; in Cyprus, *ἰατήρ*. A text at Trikka reads *ἰήτωρ*; whilst some Athenian peculiarities are *ειήτήρ*, *ἰητήρ*, and *ἰητρός*. At Beotian Thebes the word *σάκτας* was used. That the profession was held in high favour is proved by its having been assigned to the position of a *τέχνη*, and it was written of as *ἡ ἰατρικὴ ἐπιστήμη*. Public or municipal medical officers, before the Roman imperial *régime*, were called *ἰατροὶ* or *δημόσιοι ἰατροὶ*. They were nominated and elected for one or more years, and were subsidised by their city. By the period of Nero the title *ἀρχιατρὸι* had become common in inscriptions. This word at first was used to denote the royal medical attendant of Hellenic sovereigns in Syria, and it is believed was first applied in Italy to Xenophon of Cos, who was at the court of Claudius. However, for such personages *ἰατρὸς Σεβαστοῦ* was still used. Under the Empire the public medical officer's position appears in some localities to have become hereditary. For an honorarium of 500 to 700 drachmæ the public medical officer had to treat the citizens gratuitously. Both military and naval medical men are spoken of in these memorial inscriptions. A certain Hermias of Cos was employed at Gortyna during the war of 221 to 219 B.C.; and a medical officer to a fleet is referred to in a text discovered quite lately. Some six female practitioners are mentioned in these mementos. Of one of these the record has not yet been edited *in extenso*. Another was evidently much respected, for no less than three texts concerning her are extant. One of the ladies was not only *ἰατρὸς* (or *ἰατρίνη*), but also *μαῖα*. *Apropos* of this, it is singular that no female bears the appellation of simply midwife in these lapidary texts, but among them an inscribed *ex voto* to Eileithyia qualifies two medical men accoucheurs as *μαῖοι*. Eight texts relating to veterinary surgeons should be noted, but Latin inscriptions, especially from the sites of legionary camps, would augment the number of these. Athletic contests at the great games were provocative of many accidents, and so in view of casualties the committees for such sports arranged for surgeons to be in attendance. So, also, the various gymnastic associations and many societies similar to our clubs, or rather to the mediæval guilds, retained medical men for their members. The faculty themselves formed associations and councils. In one instance, at Rhodiaopolis, an enthusiastic member of the profession seems to have established a medical council in his native city or to have convened a congress there. His name was Herakleitos, and he further distinguished himself by composing medical poems. His inscriptional panegyric, therefore, properly entitles him *Ομηρος ἰατριχῶν ποιημάτων*. These contemporary memorials reveal to us other literary prodigies among medical authors

besides those familiar to fame from the classics. Thus, one inscription tells us that Hermogenes of Smyrna composed an Iatrika of 77 books. Another praises Tiberius Claudius Menekrates for writing a medical treatise in 156 books. As nearly all this kind of medical record is honorary it recapitulates all the honours presented to the individuals whom the texts concern, thus showing conclusively not only the high respect which these several members of the medical fraternity enjoyed, but also the lofty esteem in which medical men were held in the Greek and Roman world. We do not here refer to the numerous inscriptions concerning the cures and the cult of medicine in the various Asklepieia, especially at those of Epidauros, Athens, and Cos, because they relate also to the religious aspect of the matter. Many medical men at these shrines express their gratitude to the deity for guidance or for direct intervention on behalf of their patients. The corpus of inscriptions from these sites —which occupied the place of the modern clinics of to-day— is well known. But the colleges attached to them may have been of a more genuinely educational nature than has been hitherto supposed, for an inscription emanating from Ceos refers to a professor as lecturing upon *ἰατρικὴ τέχνη*, which may have meant general physiology. The life-history of the ancients can no longer be adequately written by confining research to the classic authors whose works remain to us, not even if we include the many portions of books recently recovered from among Egyptian papyri. The immense mass of inscriptions must be thoroughy investigated and the information afforded by them utilised, a fact which is better appreciated on the continent than with us.

RHEUMATIC FEVER IN THE LAST DECADE.

AN interesting paper, being the treasurer's prize essay of the Pupils' Physical Society, is contributed to Vol. LXV. of the Guy's Hospital Reports by Dr. Alexander Sandison on the subject of Rheumatic Fever in the Last Decade. The essay is divided into two parts, the first of which is devoted to a historical and critical review of the advances made in the study of acute rheumatism during the period 1900–09. The second part contains an analysis of the cases admitted to Guy's Hospital during the same period. In the first part a careful review of the observations made during the decade upon the relation of micro-organisms to the etiology of the disease is given, especial reference being made to the work of Poynton and Paine. Dr. Sandison concludes that while it is now generally admitted that rheumatic fever is probably an infective condition due to some micro-organism or organisms, the increasing isolation of Poynton and Paine and their supporters from the opinions of other workers suggests that subsequent work will support the views of those who deny the specificity of the micrococcus. He refers with some emphasis to the work of Dr. Horder, who obtained entirely negative results from the examination of the blood of 30 cases of acute rheumatism during life, and in post-mortem examinations of the effusions, vegetations, and other lesions in 16 cases, only found streptococci in five. On the other hand, in 33 examinations of the blood in cases of malignant endocarditis he obtained 28 positive results, in 18 of which streptococci were recognised, many of which might be called diplococci. There is here a possible analogy with scarlet fever, with two clinical types, an ordinary one due to an unknown micro-organism and a malignant form from which a streptococcus can be readily isolated. In other directions Dr. Sandison points out that progress has been but slight The relationship between chorea and rheumatism has been more firmly established; while, on the other hand, the importance of tonsillitis and of the various skin affections, including peliosis rheumatica, as direct manifestations of rheumatism has become less generally accepted, and iritis is not now believed to be of rheumatic origin. He expresses disappointment at the failure to advance in the direction of prevention of rheumatic heart affections, but spoke hopefully of the increasing emphasis which is now being laid upon the importance of the early diagnosis and treatment of the rheumatism of children. In the second part, dealing with the cases at Guy's Hospital, he discusses the 1053 cases of undoubted rheumatic fever which were admitted during the 10 years, representing 3·96 per cent. of the total admissions to the medical wards. Analysis of the cases shows that some variety of heart lesion occurred in at least 50 per cent., chorea occurred in 8·7 per cent., and skin lesions, erythema nodosum, and purpura in 3·9 per cent. In regard to sex, 546 were males and 507 females. Considerations of family history and diathesis are briefly examined. Out of 89 cases in which there were notes of family history, a positive result was found in 18 cases, which is 20·2 per cent. There was a predominance of the incidence of the disease among the dark type, especially those of the dark-brown hair and blue-grey eyes. A lengthy examination is made of the relation between rheumatic fever and weather conditions, and the following conclusions are arrived at. In the presence of increasing sun, temperature, and humidity the disease increases; in the absence of sun and temperature, but with high humidity, the disease continues for a while, but falls rapidly as the humidity declines; easterly winds are conducive to the disease in the presence of rising sun and temperature in spite of declining humidity. In other words, sun and temperature, aided by east winds, produce the disease and spread it abroad, while humidity maintains it. The subject of rheumatic nodules is next considered. Twenty-five cases were observed, of which 8 died—that is, 32 per cent. All of them presented heart disease in one form or another. Excluding one rather unusual case, there were 12 cases in males with an average age of 13¼ years, and 12 in females with an average age of 10½. Salicylism was noted in 17 cases of the total number of cases of rheumatic fever—namely, in 1·6 per cent. It appears to occur much more frequently in adults than in children or in young people. Dr. Sandison has afforded an interesting and useful *résumé* of the present state of our knowledge in regard to this disease. He points out that much yet remains to be done in the elucidation of its etiology, pathology, and treatment. His paper is of value in indicating the directions in which future work may proceed.

INFANT MORTALITY.

A LECTURE delivered at the Galton Eugenics Laboratory of University College, London, by Dr. M. Greenwood, jun. (of the Lister Institute of Preventive Medicine), threw some interesting light on this subject. The lecturer pointed out that public opinion respecting the possibility of influencing the infant death-rate by administrative action had greatly changed during the last 100 years, the prevalent belief being that the great majority of deaths in the first year of life were due to preventable causes. Apart from the supposed ill-effects of the industrial employment of mothers (a subject discussed by Miss Elderton in a previous lecture of the same series) three factors had been associated in the public mind with the rate of infant mortality—viz., the birth-rate, the prevalence of artificial feeding, poverty. It is usually supposed—and the supposition was again adopted in the recent Local Government Board report on infant mortality—that the connexion between the birth-rate and the infant death-rate was due to the higher fertility of the poorer classes and might be regarded as of secondary importance. In view of

the probability that stocks characterised by a high proportion of heritable defects seem more fertile than the average—a result largely attributable to systematic limitation of families among the middle and superior artisan classes—the current belief as to the nature of the association between a high birth-rate and a high infant death-rate requires critical examination. But, as Dr. Greenwood pointed out, the high mortality of bottle-fed children may, in part, be a consequence of some inherited weakness of constitution. He described the results of an analysis of data, published by Dr. Groth and Dr. Hahn, collected in the rural districts of Bavaria, and said that while he was of opinion that these data were not free from objections, he believed that the following results could be accepted—viz.: (1) both the birth-rate and the prevalence of bottle-feeding were more closely associated with the infant death-rate than was the prevalence of administrative poverty, as indicated by the proportion of inhabitants in receipt of some form of public assistance; (2) the association of the birth-rate and the infant death-rate was not secondary to an association between the latter and poverty. Dr. Greenwood was of opinion that the association between the birth- and infant death-rates was no mere fortuitous occurrence, but might find its real explanation in the artificially engendered difference of fertility between normal and pathological stocks. In this connexion the work of Dr. David Heron was, in the lecturer's view, of great significance. In the days prior to general limitation of family by the more prosperous classes 50 years ago the correlation (deduced from London statistics) between the birth- and infant death-rates was actually negative. By 1901 it had become large and positive. The general conclusion come to was that the effects of administrative reforms upon the infant death-rate were in danger of being exaggerated. Any such exaggeration was calculated to do a great deal of harm, because expectations were raised which could not be realised, and the consequent reaction in the public mind might lead to general indifference towards the subject of sanitary administration. At the present time, he thought, public health matters were discussed with a regrettable absence of the critical spirit and a large infusion of personal or party bias.

THE MYSTERY OF $C_{10}H_{16}$.

$C_{10}H_{16}$ is one of the most interesting molecular groups known to chemists, and its careful study promises to lead to developments of the utmost utility and importance to the world. But so far it has baffled man to find out, except perhaps in a few instances, how Nature moulds these groups, to form an ever-varying number of substances familiar to everyone. $C_{10}H_{16}$, for example, is the foundation of rubber, but no chemist yet has been able to handle $C_{10}H_{16}$ so as to persuade it to change from a simply constituted oil into the well-known solid, enduring, resilient substance rubber. And yet it is known quite definitely that indiarubber is practically speaking a multi- or poly-terpene, a kind of consolidated turpentine, which is the most familiar example of a terpene, the molecular formula of which is $C_{10}H_{16}$. But $C_{10}H_{16}$ is the important constituent of a number of well-known essential oils, as, for example, lemon, lime, lavender, bergamot, celery, laurel, parsley, sage, and thyme, and yet in spite of this molecular identity their properties are, of course, very different. Turpentine, for example, can hardly serve the purpose of a delicate perfume upon the handkerchief is the same way that, say, lavender does. The fact that $C_{10}H_{16}$ is a group common to both clearly does not justify the conclusion that they are available for a similar service. Modern conceptions of the constitution of matter are leaning strongly again to the view that, after all, there is but one prime material out of which all the elements, dissimilar as well as similar, as we know them, have been moulded by processes of strain, temperature, pressure, and so forth from one primordial stuff; and it is conceivable similarly that $C_{10}H_{16}$ can be made the foundation of a series of fabrics differing widely from one another but whose primordial substance after all is $C_{10}H_{16}$. Amongst modern synthetic triumphs is camphor, and here once more we encounter the $C_{10}H_{16}$ group, which is not surprising, since the starting-point of synthetic camphor is turpentine. Recently, again, it has been announced that synthetic rubber has been successfully obtained. Whatever the method is, it is pretty safe to predict that the starting-point of it must be $C_{10}H_{16}$ in some form or another, since rubber is a mere multiplication of this group $(C_{10}H_{16})n$. It is interesting to notice that both turpentine and rubber are natural exudations, the former from coniferous trees and the latter from the latex-yielding trees of South America, Africa, and India. It is evident that Nature elaborates many useful things on the basis of $C_{10}H_{16}$, and modern developments are compelling man to take a deep interest in the constitution of hydrocarbons of that type.

PAROXYSMAL TACHYCARDIA FROM A LESION OF THE AURICULO-VENTRICULAR BUNDLE.

MODERN pathology teaches that lesions of the auriculo-ventricular bundle prevent, partially or completely, the passage of the contraction wave from the auricles to the ventricles, and so produce the form of bradycardia known as heart-block. At a meeting of the Société Médicale des Hôpitaux of Paris recently M. A. Cade and M. J. Rebattu reported a case in which, on the contrary, a lesion of the bundle appeared to cause paroxysmal tachycardia. A woman, aged 71 years, was admitted into hospital. In the previous year she had a "stroke," which was followed by hemiplegia which gradually regressed. During this period she was an in-patient at the Hôtel Dieu, where typical attacks of paroxysmal tachycardia were observed. They began 15 years previously. The attacks commenced suddenly and were marked by a feeling of suffocation, violent palpitation of the heart, and præcordial pains. Often there were associated digestive troubles—constipation, anorexia, nausea, salivation, and furred tongue. The pulse rose to from 170 to 200, but was regular. Auscultation showed well-marked embryocardia. The jugular veins were distended and pulsated visibly. The face was first pale, then sallow. Often the right hypochondrium was tender. The urine was scanty. Some attacks were accompanied by albuminuria, slight œdema of the legs, and pulmonary congestion. The attacks usually lasted some days, and could be cut short by vomiting, spontaneous or induced by the administration of ipecacuanha. In the intervals the pulse was 60 or 70, and auscultation of the heart revealed nothing. The radial arteries were tortuous, the arterial tension was raised, and aortic pulsation was visible in the suprasternal fossa. The patient died suddenly during an attack. The necropsy showed pleural adhesions and old tubercles at the apices of the lungs. The kidneys were of normal volume, their surfaces were slightly granular, and their capsules were adherent. The liver was slightly indurated. The heart was large and weighed 425 grammes. There were some patches of atheroma on the aortic valves, and the mitral valve and aorta were very atheromatous. In the right lenticular nucleus was an ochreous focus, the remains of an old hæmorrhage pressing on the internal capsule. There were no lesions of the mediastinum to suggest pressure on nerves. Microscopic examination showed well-marked lesions of the auriculo-ventricular bundle. It was in great part converted into fibrous tissue, and the muscular fibres which remained were

degenerated. Further, the bundle showed signs of recent inflammation in the form of an abundant infiltration with leucocytes. The pathology of paroxysmal tachycardia is obscure; no constant changes have been found to account for it in the cardiac muscle, ganglia, or nerves. It has generally been attributed to some disorder of cardiac innervation. When bradycardia was shown to be due to destruction of the auriculo-ventricular bundle the question naturally arose, Is paroxysmal tachycardia due to its irritation? The first observations on the point were made by Dr. James Mackenzie, who found in one case obliteration of the nutritive artery of the bundle with alteration of the latter, and in another fibrosis of the sino-auricular node. In a case recorded by Vaquez and Esmein a recent lesion—infiltration of the bundle with embryonic cells—was found. These "choked" the muscular fibres, causing degeneration of some of them. M. Cade and M. Rebattu concluded that paroxysmal tachycardia is due to abnormal irritability of the auriculo-ventricular bundle, which may be purely functional or provoked by lesions. In favour of this view was the fact that in some cases in the intervals between the attacks extra-systoles originating in the auriculo-ventricular bundle had been observed. Paroxysmal tachycardia might thus be regarded as an aggregation of extra-systoles. Moreover, a lesion which irritated the bundle might be expected in time to diminish or abolish its conductivity and produce bradycardia. Of this there was clinical evidence, for cases had been recorded in which tachycardia has ended in bradycardia or alternated with it.

RAT-BITE DISEASE.

THE curious condition known as rat-bite disease, or rat-bite fever, attracted some attention in this country two years ago, when Dr. T. J. Horder published an account of three cases in the *Quarterly Journal of Medicine*, and Dr. G. S. Middleton described a fourth in these columns.[1] Up to that time almost the only researches into the disease had been carried out in Japan, where it would seem that opportunities of clinical observation are much more numerous than in any other civilised country. In a critical review of the subject by Dr. F. Proescher, which is published in the last volume of *International Clinics*, a full summary of the now somewhat extensive literature is given, together with the account of a case which was investigated by him with exceptional care and thoroughness. Rat-bite fever is an infective disease *sui generis* transmitted through the bite to human beings; it is probably a primary disease of the rat, comparable with hydrophobia, which is primary in canines. The bite is not constantly, but is very often, followed by the disease, which is endemic only in Japan and sporadic in China; elsewhere it is rare, or at any rate seldom recognised. Experimentally Dr. Proescher has transmitted the disease to animals (guinea-pigs), and he states that Ogata has done the same. The latter has described an organism allied to the neosporidia, which he thinks is the specific cause of the disease; Dr. Proescher did not encounter it, but found the excised tissues from around the bite upon his patient to be full of an organism somewhat resembling that of hæmorrhagic septicæmia. He also found the same organism in smaller numbers in some of the guinea-pigs to which he succeeded in communicating the disease clinically. Middleton's diplococcus he regards as a secondary infection, and he makes the same suggestion with regard to Ogata's protozoon, subject to the proviso that the Japanese fever differs in several respects from that in other countries and may not be the same disease. The incubation period of rat-bite fever is variable, with or without prodromata. The initial symptoms are usually chills, pyrexia, and painful inflammatory reaction at the site of the bite, which has generally healed. Vesicles and pustules then form at this site and occasionally the tissues become gangrenous. A lymphangitis develops, with swelling of the proximal glands. The constitutional symptoms include malaise, weakness, nausea, headache, anorexia, thirst, articular and muscular pains, sweats, and in rare cases delirium, hallucinations, coma. Death sometimes results, but only after several months of progressive cachexia. The liver and spleen are not enlarged, nor has icterus been reported; loss of reflexes, with sensory and motor paralysis, is often present in serious cases. The treatment recommended includes cauterisation and disinfection of all recent rat-bites, and in the case of the developed disease excision of the wound or cicatrix. Other symptoms are to be treated as they arise, for at present there is no specific remedy; a liberal and nourishing diet is an essential part of the treatment.

[1] THE LANCET, June 11th, 1910, p. 1618.

AMŒBIC DYSENTERY.

IN the biological laboratory of the Bureau of Science at Manila (*vide* the *Philippine Journal of Science* for October last), Dr. Ernest Linwood Walker has recently been making a comparative study of the amœbæ discovered (1) in the water-supply of the city of Manila, (2) in the intestinal tract of healthy individuals, and (3) in the alimentary canal of patients attacked by amœbic dysentery. Some of the results of this important inquiry help us towards a better understanding of the etiology of this disease. It was found by Dr. Walker that the amœboid organisms in the town's public water-service belonged to the genus amœba (Ehrenberg), as also did those which could be cultivated from the bowel discharges of healthy persons, or of those suffering from amœbic dysentery. The cultivable species of the genus amœba are not, however, according to this investigator, parasitic in the human intestinal tract; when obtained in culture from that source they are probably, he thinks, derived from cysts of amœbæ which have been ingested with water or food, and which have passed through the alimentary canal. The amœboid organisms which are parasitic in the intestine of man belong to a distinct genus, the entamœba (Cassagrandi and Barbagallo); they are, in Dr. Walker's opinion, strict obligatory parasites, and are incapable of multiplication outside the body of their host, nor can they be cultivated on Musgrave and Clegg's medium. One non-pathogenic species of the genus entamœba is recognised by Dr. Walker—namely, E. coli (Schaudinn)—which includes E. nipponica (Kordzumi), and which develops cysts containing eight nuclei. Another species of entamœba—namely, E. histolytica (Schaudinn), is presumed to be pathogenic, and includes E. tetragena (Viereck); it develops cysts containing four nuclei. A differential diagnosis of an infection with E. coli and one with E. histolytica can, according to Dr. Walker, be made with the microscope, and such infection in either case must always come directly or indirectly from a previous case. Water or uncooked food can transmit amœbic dysentery only after contamination with fæcal matter from a person suffering from the disease. It is important in this connexion to note that infection with E. histolytica may persist for an indefinite period after the symptoms of amœbic dysentery have disappeared, during which time the resistant encysted entamœbæ may be passed in large numbers in the stools and in this way become a grave source of infection to other persons. Such instances are to be regarded as carriers of amœbic dysentery, and are comparable with the recognised carriers of enteric fever or cholera. The prophylaxis of amœbic dysentery is sufficiently indicated in what has been already stated. The measures to be employed should obviously be the same as those which

are employed to prevent the spread of other specific infectious diseases of the intestinal tract, more particularly enteric fever and cholera. Dr. Walker is now engaged in carrying on an experimental study of the parasitism and pathogenicity of the species of the genera amœba and entamœba established by his present study. The results of this further research will be presented in another paper, and will in all probability be published in a future number of the *Philippine Journal of Science*.

CURIOUS CASES OF INCOMPATIBILITY.

IN a recent issue of an American pharmaceutical journal attention is drawn to the fact that an incompatibility between a medicine given internally and one applied externally may cause undesirable epidermal manifestations. Reference is made to a case in which hydrogen peroxide was applied externally, while potassium iodide was given internally. The result was a severe burning of the skin, the cause of which was not discerned for some little time. In another instance a colourless tincture of iodine, taken internally, in conjunction with an ointment of ammoniated mercury, externally applied, caused severe irritation of the skin, which was attributed to the toxic action of mercuric iodide. Other illustrations might be given of the importance of avoiding such cases of incompatibility. Thus, sulphur given internally and a solution of mercury used externally may be expected to cause a deposit of black mercuric sulphide in the skin These instances are of great interest to physicians as they afford an explanation of phenomena which might sometimes be attributed to idioscyncrasy or some other cause, except the right one. Within the last few months an interesting case arose at St. Paul, Minn. A lady had used a certain advertised face-cream for the purpose of removing freckles, and she was horrified to find that her face became variegated in colour from yellow to brown and then to black. Since many creams of this nature contain some form of mercury it is probable that the trouble was caused by a chemical reaction between the ingredients of the cream and some medicinal substance she may have been taking at the same time. These illustrations emphasise the danger of indiscriminate self-medication; they further show that care should be taken not to use mercurial creams when undergoing certain courses of internal medication. The apparently harmless sulphur lozenge or compound licorice powder may cause much chagrin and discomfort, if not danger, when taken into the system at a time when a favourite brand of toilet cream is being used to beautify the complexion.

AORTIC ANEURYSM MISTAKEN FOR ASTHMA.

IN the *Interstate Medical Journal* for January Dr. Solomon Solis Cohen has published a note on two cases of aortic aneurysm, in which the unusual mistake was made of diagnosing asthma. Both patients were syphilitic labourers who were suddenly attacked with dyspnœa, which was the only symptom. The ordinary signs of aneurysm—pulsation, thrill, and bruit—were wanting. There was constant dyspnœa with paroxysms of increased distress accompanied by sonorous and sibilant râles. The patients were sent into hospital with the diagnosis of asthma. They sat upright in bed, labouring for breath, with marked suprasternal recession in one case and supraclavicular recession in the other. There was laryngeal stridor; in the former case loud, and both inspiratory and expiratory; in the latter, low and expiratory only. In both cases the vessels of the neck throbbed violently and the jugular veins were much distended. In the former case there were attacks of syncope. In both cases Dr. Cohen made at sight the diagnosis of obstructive dyspnœa, possibly aneurysmal. Careful physical examination revealed limited dulness beneath the manubrium sterni—in the former case, of about the size of a shilling; in the latter, of a dollar, and therefore extending somewhat to the right and left of the bone. In neither case was any thrill, bruit, or pulsation detected, nor did the laryngoscope show anything. In both cases a skiagram revealed a shadow above the heart, which was interpreted as a dilated aortic arch pressing upon the root of the trachea. In the former case the shadow was small and circular; in the latter, large and somewhat pear-shaped. The former patient died, and the necropsy showed a sac more than an inch in diameter, of which tough clot and the anterior wall of the trachea formed the posterior wall, while it communicated by a small opening with the transverse arch. What makes the cases worthy of record is that sudden dyspnœa was the sole symptom; the ordinary signs of aneurysm were wanting; and incidentally to the constant dyspnœa paroxysms of increased distress, with wheezing and râles, misled the medical attendants to a diagnosis of asthma. But the suprasternal recession and stridor, indicating obstruction of the larynx or trachea, were incompatible with asthma. The possibilities were mediastinal growth or gumma, enlarged bronchial glands, peritracheal abscess, and aneurysm pressing on the air passages.

THE TREATMENT OF GONORRHŒAL CONJUNCTIVITIS WITH STEAM.

A NOVEL and somewhat drastic method of treating gonorrhœal conjunctivitis has lately been advocated by Dr. W. Goldzieher in the *Wiener Klinische Wochenschrift* (November, 1911). The procedure is based on the facts that the gonococci are rapidly killed by a temperature slightly exceeding that of the normal body temperature, and that they are situated in the epithelial layer of the conjunctiva, their presence in the subepithelial layer being of rare occurrence. As compared with the mucous membrane of the male urethra, the conjunctiva is superficial and easily exposed, and it therefore lends itself to local treatment by heat. Dry heat is liable to injure the cornea by the withdrawal of fluid, and steam is therefore preferable. It was generated by electricity in a boiler small enough to be as easily manipulated as any other instrument for operations on the eye. Below the tube through which the steam escaped another tube was fitted to catch the drops of condensed steam which would otherwise have scalded the patient's face. The temperature of the steam impinging on a screen at a distance of 4 centimetres from the mouth of the tube was found to be 113° F. This temperature causes considerable pain, and cocaine is valueless, for it has no influence on the sensations of heat and cold. After a while, however, the treatment becomes so painless that even children stand it easily. No ill-effects resulted from the treatment, but some difficulty was experienced in everting the swollen and brawny upper eyelids, which sometimes required the application of iced compresses to reduce the infiltration. The delay thus caused is not, however, serious, for corneal infiltration or ulceration seldom occurs at this stage. As soon as the eversion of the eyelids is practicable, the conjunctival sac is first syringed with a solution of permanganate of potash, and it is then dried with a strip of gauze, after which the steam is applied. When there is much chemosis, the ocular as well as the palpebral conjunctiva should be steamed, great care being taken to avoid injuring the cornea. The skin in the neighbourhood of the eyes is protected from the steam by layers of linen or wet gauze. In the course of three months 15 cases were thus treated. All these were severe, and in 5 cases ulceration of the cornea existed at the commencement of the treatment. The gonococcus was invariably present, and with the exception of a

boy, 7 years old, all the patients suffered from urethral or vaginal gonorrhœa. The 10 patients whose corneas were not involved at the commencement of the treatment made a rapid and complete recovery, the chemosis and discharge having practically ceased in four days' time. In the case of the 5 patients whose corneas were already involved, the conjunctivitis was cured and was no longer a source of infection to others; and in 1 case complete recovery of the cornea was also effected. Although the steam rapidly reduces the discharge, some conjunctival swelling may persist for a time, as the steam tends to relax the blood-vessels and thus cause passive hyperæmia. It is unnecessary to reduce this swelling by the application of silver nitrate, for syringing with permanganate of potash is sufficient. Comparing the above method with the silver nitrate treatment, Dr. Goldzieher points out that the latter is very imperfect, as it forms a deposit in the epithelium which becomes impermeable, and thus prevents the further action of the nitrate on the deeper layers of the conjunctiva. The gonococci also lurk in epithelial crypts and in the upper fornix where they are difficult to attack with silver nitrate. He, therefore, concludes that his treatment is the better of the two, although it requires considerable technical dexterity. Possibly also cases may exist which are refractory to it.

THE joint meeting of the Surgical, Medical, and Anæsthetic Sections of the Royal Society of Medicine to discuss Partial Thyroidectomy under Local Anæsthesia, with Special Reference to Exophthalmic Goitre, held on Feb. 27th, has been adjourned to a special meeting on Tuesday, March 5th, at 5 30 P.M., at the Royal Society of Medicine, 15, Cavendish-square. Dr. W. J. McCardie, president of the Anæsthetic Section, will be in the chair. The following will take part in the debate: Mr. Charters Symonds, Mr. A. E. Barker, Mr. Donald Armour, Mr. Walter Edmunds, Dr. J. Blumfeld, Mr. C. H. Fagge, Dr. H. J. Scharlieb, Dr. G. A. H. Barton, Mr. Rupert Farrant, and Mr. James Berry.

THE National Organisation Committee for the Berlin Congress of Obstetrics and Gynæcology, to be held in September next, have elected Sir Alexander Russell Simpson, Dr. Macnaughton Jones, and Dr. Herbert Spencer as delegates for the United Kingdom. Dr. Macnaughton Jones has also been appointed *rapporteur* on the subject of the Surgery of the Peritoneum.

Sir Richard Douglas Powell is giving two emeritus lectures to-day, Friday, March 1st, and on Friday, March 8th, at 3 P.M., in the small theatre of the Middlesex Hospital Medical School on the Medical Aspects of Life Insurance.

MEDICAL SICKNESS AND ACCIDENT SOCIETY.—The usual monthly meeting of the executive committee of the Medical Sickness, Annuity, and Life Assurance Society, was held at 429, Strand, London, W.C., on Friday, Feb. 16th. There were present: Dr. F. de Havilland Hall, in the chair; Dr. F. C. Martley, Dr. J. Pickett, Dr. Frederick S. Palmer, Dr. W. Knowsley Sibley, Dr. F. J. Allan, Dr. M. Greenwood, Dr. H. A. Sansom, Mr. J. Brindley-James, Mr. F. S. Edwards, Mr. E. Bartlett, Dr. J. W. Hunt, and Dr. J. B. Ball. The winter season always produces a considerable excess of sickness claims over the summer-time, and in the early part of this year the Medical Sickness Society has experienced a large number of these claims. But although numerous these claims have been for the most part of unusually short duration and have not caused any serious addition to the amount usually expended in this way. The society's business continues to be very successful and the invested reserves now amount to over a quarter of a million sterling. Prospectuses and all further particulars on application to Mr. F. Addiscott, Secretary, Medical Sickness and Accident Society, 33, Chancery-lane, London, W.C.

AN EXAMINATION OF THE MEDICAL PROVISIONS OF THE NATIONAL INSURANCE ACT.

BY WILLIAM A. BREND, M.A. CAMB., M.B., B.SC. LOND.,
OF THE INNER TEMPLE, BARRISTER-AT-LAW; LECTURER ON FORENSIC MEDICINE, CHARING CROSS HOSPITAL.

IV.[1]

The Insurance Act and Public Health.

AS some of the fundamental objects aimed at by the Insurance Act are the reduction in the total amount of disease throughout the country and the establishment of more hygienic conditions among the working classes, it is desirable that the scheme should coöperate with the public health service. Several provisions arrange for this. The association of the Local Government Board with the Commissioners in the administration of sanatorium benefit is an instance. Another is furnished by Section 60, which requires an Insurance Committee to make such reports as to the health of insured persons as the Insurance Commissioners, after consultation with the Local Government Board, may prescribe, and to furnish statistical and other returns. It further empowers the Insurance Committee to make such other reports on the health of insured persons and the conditions affecting them as they think fit. The Insurance Commissioners are required to send copies of these reports to the various county and other councils which appear to be affected or interested. Presumably arrangements will be made for the compilation of reports by persons specially qualified. There is no authority in the Act for imposing the duty of preparing them upon the medical practitioners who are giving attendance and treatment under medical benefit.

The Insurance Committee is also required to make such provision for the giving of lectures and the publication of information on questions relating to health as it thinks necessary or desirable, and may, if it thinks fit, for that purpose make arrangements with local education authorities, universities, and other institutions. This may be a useful provision for disseminating knowledge of hygiene among the working classes.

With a view to promoting co-operation between Insurance Committees and county councils, &c., Section 60 (2) empowers any medical officer of health at the request of an Insurance Committee, and with the consent of the council by whom he is appointed, to attend meetings of the committee and give such advice and assistance as is in his power.

Perhaps the most important provisions from the public health point of view are those contained in Section 63, dealing with the reduction of sickness from preventable causes. Where it is alleged that there is an excessive amount of sickness among insured persons due to the conditions or nature of their employment, or to bad housing or insanitary conditions in any locality, or to an insufficient or contaminated water-supply, or to neglect on the part of any person or authority to observe or enforce the provisions of any Act relating to the health of workers in factories, workshops, mines, quarries, or other industries, or relating to public health, or the housing of the working classes, a claim may be sent to the person or authority in default, for payment of the extra expenditure incurred in consequence. Failing the settlement of such claim an inquiry may be held by a person appointed by the Local Government Board, and if at such inquiry it is shown that the amount of sickness has (1) during a period of not less than three years before the date of the inquiry; or (2) if there has been an outbreak of any epidemic, endemic or infectious disease, during any less period; been in excess of the average expectation of sickness by more than 10 per cent., and the sickness was due to any such cause as stated, the person, company, or local authority responsible is required to make good the extra expenditure which has been caused by the neglect. The effect of these provisions in stimulating negligent local authorities to an efficient discharge of their public health duties may be of considerable value.

But the effect of the Insurance Act upon public health

[1] Articles I., II., and III. were published in THE LANCET of Feb. 10th (p. 383), 17th (p. 447), and 24th (p. 524).

may not be confined to these matters with which its provisions directly deal. An entirely new situation is created from which various evils afflicting the community must be viewed afresh. Take, for example, the question of State action to reduce the transmission of syphilis. It is recognised that the harm done by this scourge is second only to that resulting from tuberculosis itself, and as far back as 1904 the Committee on Physical Deterioration recommended that an exhaustive inquiry should be made into the extent of the malady and the steps that might be taken to arrest its progress. But nothing as yet has been done. It is, of course, a difficult matter to deal with, and the social and moral interests involved demand the fullest consideration. But as the State has now made itself responsible for the treatment of these diseases among insured persons, no fresh principle is involved in instituting such preventive measures as are practicable and desirable. If the new methods of treatment of syphilis should prove to possess all that is claimed for them, the administrative difficulties will be sensibly lightened.

It is to be hoped, too, that the acceptance by the State of these additional responsibilities of a medical character will bring into prominence the necessity for coördination among the various Government departments charged with the administration of matters demanding medical knowledge. At present there are separate medical staffs in the Local Government Board, the Home Office, the Board of Education, the Registrar-General's Office, and other departments, each independent and uncoördinated with the others. There is not even uniformity in so fundamental a matter as the classification and nomenclature of disease. Different departments divide the country up into different areas, so that for local purposes the value of their statistics is seriously diminished. Specialisation of function leads to neglect of interests on the one hand and overlapping on the other. In 1910 four separate departments of State dealt specially with tuberculosis in their reports and three with infant mortality. Ardent reformers have long dreamed of the establishment of a public health department which should manage all the various medical services now scattered through so many offices, and have at its head a Minister of Cabinet rank. The realisation of such a project is brought sensibly nearer by the Insurance Act.

The Future of Medicine under the Act.

A note of warning has been sounded by Sir Clifford Allbutt concerning the influence of the Insurance Act upon the future of medicine. In the *Times* of Jan. 3rd the eminent professor called attention to the fact that many of the men who are now entering medical practice are trained in highly scientific methods for the diagnosis and treatment of disease. They are versed in the new pathology of the blood; can make bacteriological examinations; investigate the morbid characters of secretions; and employ with skill the instruments of precision which science has given to medicine. Sir Clifford Allbutt points out that modern treatment depends increasingly upon accuracy of diagnosis which can only be attained by the use of such methods. He takes as an instance the diagnosis of a syphilitic aneurysm in the chest, which has been recognised by a laryngoscopic examination of the throat revealing paralysis of a vocal cord, and confirmed by the performance of a Wassermann test. Such proceedings demand time and money, and he asks if they are to be denied to the poor countryman who is able to do some work and cannot spend all his time in a hospital.

Sir Clifford Allbutt writes as though these advantages were at present at the service of the working-class, which is certainly very far from being the case. No medical man would attempt to defend the conditions under which much of the medical attendance among the poor is given. And is his view justified that the conception of medical treatment in the Act is the old-fashioned one of the village club which prescribes drugs and mixtures for all diseases? Do not the clauses in Section 16, empowering the Insurance Commissioners to retain certain sums of money to be applied in accordance with their regulations for the purpose of research, bear witness to the fact that the development of the scientific side of medicine has not been lost sight of? The amount available under these clauses will be about £60,000. The same may be said of the sections already quoted, providing for the giving of lectures and linking the scheme up with the universities and other educational centres.

But looking at the matter from a broad point of view, is it likely that so important a consideration will be neglected in a service which contains representatives of the medical profession upon practically every governing body? It is, indeed, essential in order to secure the objects aimed at by the Act, that the most modern and complete methods of diagnosis and treatment should be available, and in the long run their provision will make for economy. The matter is undoubtedly one which lies very much in the hands of the protession itself. Only medical men can judge what is required, and it is for them to formulate their demands. The lay authority which deliberately ignored the expressed opinion of the profession, that the service did not provide for up-to-date methods of diagnosis, would incur a heavy responsibility. It would be out of place here to consider what should be provided or how it should be done, but one suggestion may be put forward. Many of the special methods of investigation require a laboratory for their performance. There is nothing in the Act to prevent the establishment by the Commissioners in every district of a clinical research laboratory, whether in association with an anti-tuberculosis dispensary or not. In these laboratories local practitioners could either make their own investigations or have them performed for them by skilled pathologists.

The "Six Points."

Although the situation as regards the "six points" has been modified it is worth while bringing forward some considerations respecting them, since the opinion is largely held that they should have been embodied in an Act of Parliament or guaranteed by the regulations before further steps were taken by the profession. Perusal of the six points soon leads to the conclusion that such a course as that proposed could not be followed until the meaning of some of them at least has been much more clearly defined. Indeed, the impression is created that they were never intended to become statutory in their present form, but merely to serve as a basis for discussion.

The first is the demand for "an income limit of £2 a week for those entitled to medical benefit." It is clear that this does not express what the profession really wants. There is no objection to a person with any income receiving medical benefit so long as it takes the form of a cash contribution to one possessing means over a certain limit. It is the medical treatment of such a person at a fixed fee that is resented. The administrative difficulties in the way of dealing with this matter by Act of Parliament have probably been overlooked. No time over which the average is to be calculated is specified. Suppose a man is working for one period for one employer at a certain rate, is out of work for a time, and then works for another at a different rate, upon what principle is his weekly income to be calculated? What, moreover, is income? Are the earnings of a wife or child to be included, or the rent received from letting a room to a lodger? How is the information to be obtained from illiterate persons? The clerical staff required to make these assessments and the expense of so doing would be enormous.

The above difficulties apply with far less force to the modified powers of fixing an income limit given to the Insurance Committees. There is a great deal of difference between the rigidity of an Act of Parliament and the elasticity of regulations which can be modified according to person and circumstance. In some cases, for instance, medical committees may be content to accept average wage instead of income, an easier thing to assess. In other cases they may be satisfied with a simple declaration by each insured person, accompanied by a right on the part of the medical committee to investigate the circumstances of any person who is believed to have an income exceeding the amount agreed upon. It may be said that such a right is all it is sought to embody in an Act, but then it ceases to be the "point," and the demand is that the point shall be agreed as a preliminary to discussion.

Free choice of doctor and administration of medical benefit have been considered.

The fourth point requires the method of remuneration of medical practitioners adopted by each Insurance Committee to be according to the preference of the majority of the medical profession in the district of that committee. The same result can be achieved by the profession without further action either by Parliament or the Commissioners. In any district the practitioners on the panel can pool the amount or

amounts received from the Insurance Committee and distribute the total among themselves upon any principle they please. Such a system is in force in some parts of Germany and is said to work satisfactorily.

The fifth point runs, "Medical remuneration to be what the profession considers adequate having due regard to the duties to be performed and other conditions of service." The briefest consideration will show that this requires a great deal of discussion before it could be incorporated in an Act of Parliament or in regulations. What, for this purpose, is the profession? Does it mean every man on the Medical Register, or only those who are in practice, or those who are going to undertake medical treatment and attendance under the Act? How are the duties and conditions to be known until the regulations are framed? What meaning is to be attached to the word adequate? Finally, how can any scheme with financial provisions be based upon so vague a foundation as that "remuneration is to be adequate"? In a draft amending Bill which has been published this point has been dropped and a minimum capitation fee named instead. But there is no evidence that this represents the opinion of the "profession," or that it is "adequate."

Similar criticisms apply to the last point, which asks for "adequate" medical representation on the various controlling authorities.

The position is now governed by the resolution of the Representative Meeting on Feb. 21st, instructing the Council to require that "the minimum demands of the British Medical Association be embodied in the regulations to be issued by the Commissioners in such a manner as shall be effectual and permanent, with a view to having the same embodied in an amending Act." With this must be coupled the resolution providing for medical representatives to be appointed on the Advisory Committee which is to assist the Commissioners in framing the regulations. The significance of the change from "six cardinal points" to "minimum demands" in the first resolution is not quite clear, and it is impossible to tell from the published report of the meeting which of the numerous resolutions of varying importance and embodying new as well as old principles are to be regarded as containing minimum demands, and which are not. Until this is determined, criticism must be withheld.

Dispensing.

But one new principle deserves considering on its merits, without prejudice to the question of its inclusion in the minimum demands. This is contained in the resolution:—

> That dispensing, as hitherto, should be done or arranged for by the medical practitioner for his own patients should he so desire, and paid for at the scale of tariff rate agreed upon for pharmacists by the Pharmaceutical Society.

The section in the Act dealing with dispensing by medical men is contained in 15 (5) ii., which runs: "Except as may be provided by regulations made by the Insurance Commissioners no arrangement shall be made by the Insurance Committee with a medical practitioner under which he is bound or agrees to supply drugs or medicine to any insured persons." It will be seen that while the prohibition is general the Commissioners can modify it by regulation. Whether they can go so far as to permit dispensing by every practitioner who wishes to do so is open to question.

Drugs and medicines are to be provided by persons and firms who have agreed to do so according to such scale of prices as may be fixed by the Insurance Committee under regulations made by the Commissioners. There is nothing in the Act requiring the Insurance Committees or Commissioners to agree with the Pharmaceutical Society, and there has been no published intimation that the Society would accept the duties imposed upon it by the above resolution.

The value of retaining the right to dispense has perhaps been exaggerated. In computing the amount he will receive out of an inclusive capitation fee, a medical man is apt to deduct the amount which will go to the chemist, and forget to add his own saving on drugs. What will really be lost is the retail chemist's profit, and this is not likely to be excessive. Against this must be placed the work and time that will be saved. Moreover, dispensing under the Act will not be quite so simple as in private practice. A Government department spending public money must employ business methods, and presumably some system of requiring vouchers, &c., for expenses will be established. This will necessitate the keeping of separate dispensing accounts for insured and private patients.

Perhaps the most important consideration is not in relation to the Act but to the position and status of the profession in the future. The evils resulting from unqualified practice have been repeatedly pointed out, and one result of the Insurance Act will be to strengthen the position of the profession in demanding that this abuse be suppressed. One of its most insidious forms is prescribing by chemists. If the profession, in the matter of dispensing, places itself in precisely the same position as retail chemists, it will weaken its demands that the latter shall not undertake the functions of doctors.

Other Suggestions.

In the course of these articles some suggestions have been made of provisions which might reasonably be incorporated in the regulations. It may be convenient to summarise these:—Every insured person, whether a member of an approved society or deposit contributor, to be medically examined before being accepted for treatment at ordinary rates. Special remuneration to be paid for the treatment of bad lives, and for operations, consultations, and other "extras" by agreement. A special fee to be paid to medical men called in under the Midwives Act of 1902. Medical attendance and treatment not to include the giving of certificates for the purpose of administration of sickness and disablement benefit. Medical practitioners to be remunerated from sanatorium benefit for the special treatment of cases of tuberculosis. All complaints of unsatisfactory attendance by medical practitioners on the lists to be submitted in the first instance to the medical committees. The committees also to have the right of investigating cases of alleged malingering by insured persons. Facilities to be given for the application of modern methods of diagnosis and treatment. Patent and proprietary drugs not to be prescribed.

The Medical Profession and the State.

Whatever the final result may be, it is a matter for profound regret that the agitation of the last nine months should have arisen. Members of a profession, justly renowned for its altruism, cannot but deplore that circumstances should have forced them to take up an attitude of hostility towards a measure designed for the benefit of the sick. But the present position is not a new one. The Insurance Act affords the latest instance, and one on a large scale, of the unsatisfactory way in which matters demanding medical knowledge have been dealt with by the State. In some cases, as, for example, the Midwives Act and the Notification of Births Act, the interests of the profession have been neglected. More important are the cases in which the community has suffered. It would seem as though in dealing with matters demanding medical knowledge Parliament does not always grasp the importance of familiarity with the conditions under which that knowledge is to be applied, and the necessity of giving to scientific men the power of dealing with questions involving scientific principles. Many instances might be cited, but two will suffice. Consider the efforts which have been made to secure the purity of foodstuffs. Since 1875 there have been at least 12 Acts or amending Acts dealing with specified foods or foodstuffs generally, as well as Public Health Acts and Local Government Acts dealing with them incidentally, yet many of the commonest foods are adulterated or contain injurious preservatives. This is in part due to a system which may call upon a lay sanitary authority, bench of justices, or stipendiary magistrate to decide whether or not a particular substance is injurious to health, and other questions involving knowledge of chemistry, physiology, and hygiene. The Workmen's Compensation Act provides another instance. The statutory provisions enabling purely medical questions to be determined by medical men are so hedged in by restrictions as to be largely ineffective, and county court judges have frequently to decide between conflicting medical evidence and to exercise knowledge of medicine and surgery.

Perhaps even more serious is the indefinite postponement of important recommendations. Fifteen years ago a Select Committee on the Registration and Certification of Death pointed out the dangers of the present system and advised drastic alterations in the law, but no Government action has yet been taken. The failure to act upon the recommendation of the Committee on Physical Deterioration that the prevalence of syphilis should be investigated is another instance. But the most striking illustration is afforded by the Insurance Act itself. One of the difficulties confronting the actuaries was the scanty knowledge available of sickness rates, and

some of their estimates are only approximations in consequence. Yet the above-mentioned Committee recommended in 1904 "as in the highest degree desirable" that a Register of Sickness should be established and maintained. Such a Register now would be of the greatest value.

It is possible that this unfortunate state of affairs arises partly from the fact that the medical profession is so poorly represented in the legislature. Out of 670 Members of the House of Commons, there has never at any time been more than a handful of medical men. There have only been one or two in the minor posts of the Government, and there has never been a medical man in the Cabinet or at the head of an administrative department. Contrast this with the conditions in France, where last year in the legislative body 59 deputies, 37 senators, and two Ministers of State were members of the medical profession; or with the legal profession in this country, which has something like 150 members in Parliament.

The absence of medical counsel in public affairs is a serious drawback, for the medical man is peculiarly fitted to take part in social legislation. Unlike the lawyer, who venerates precedent, his training teaches him to look forward and welcome progress. His experience familiarises him with the conditions of life among the poor and gives him a knowledge of human nature. It is permissible to hope that the Insurance Act will at least have the effect of bringing to the medical profession a stronger sense of its civic duties and opportunities.

For matters of moment remain to be dealt with. In the future, steps must be taken to suppress the evils resulting from the operations of cancer curers, consumption specialists, and quacks of all kinds. The indiscriminate sale of worthless or harmful proprietary medicines to the ignorant poor, and the anomaly whereby a State which declares abortion to be a crime derives part of its revenue from the sale of abortifacients, call for suppression. The fourteenth century procedure of the coroners' courts, which allows a layman assisted by a jury of working men to determine whether an anæsthetic was necessary and was duly and properly administered, must be changed. More scientific methods are required in apportioning responsibility for crime. The problems of the feeble-minded and the inebriate will only be solved by the aid of medical science. The medical profession has a great past and noble traditions; it must look forward to a greater future and the playing of a more active part in the life of the nation.

ANNUAL REPORT OF THE PRESIDENT OF THE LOCAL GOVERNMENT BOARD.[1]

ALTHOUGH this report is mainly concerned with Poor-law administration Mr. John Burns takes occasion to discuss many subjects of which the bearing is definitely medical, and which therefore deserve consideration in our columns.

It is matter for congratulation that the decrease in pauperism reported in 1909 has since been fully maintained. Comparing the total number relieved on New Year's Day, 1910, with the corresponding facts for 1911, we learn that there was a decrease at the latter date amounting to 4·7 per cent. From comparative statistics it appears that whilst the ratio of pauperism to population did not exceed 24·5 per 1000 in the county of Carmarthen and 24·6 in Worcester, it amounted to 41·3 per 1000 in the county of Anglesey. On Jan. 1st, 1911, the average rate of pauperism to population in England and Wales was 24·9 per 1000. This rate is lower than any of the rates for the corresponding dates in the previous nine years.

Old Age Pensioners.

In the course of the year under notice 5077 persons, mostly men, aged 70 years or upwards, became old age pensioners, and consequently ceased to be chargeable to the guardians as paupers.

Insane Paupers; The "Won't Works."

In certain respects the records of pauperism are unsatisfactory. In the first place, the number of insane poor returned by the Commissioners in Lunacy still continues to show a steady increase; secondly, the adult able-bodied paupers, the "won't works," relieved during the parochial year ended Lady Day last, were more numerous than in any previous year, with the single exception of 1910; and, thirdly, it appears that in the course of last year 552 casual paupers were convicted under the Vagrancy Act, the majority either for refusing to perform the prescribed task of work or else for absconding.

Boarding-out of Pauper Children.

Although in recent years the number of children supported out of the rates has somewhat increased, nevertheless, when compared with the number similarly circumstanced 25 years ago, there has been in later years a considerable decrease. It is gratifying to learn that in the year 1910 nearly two-thirds of the pauper children in England and Wales were supported in institutions other than workhouses and union infirmaries. In the course of the last decade the number of children boarded out has risen from 7547 in the year 1901 to 9669 in 1911. On the first day of the last-mentioned year the total number of children of school age (3–14 years) maintained at the public expense was 45,605, only 312 of whom were educated in "workhouse schools," which, accordingly, may now be said to have practically ceased to exist. Almost all the pauper children are educated in public elementary schools approved for that purpose by the Local Government Board.

Emigration of Pauper Children.

The practice of sending to Canada orphan or deserted pauper children has been continued during the year with the happiest results. The reports of the Dominion immigration officers received through the High Commissioner for Canada show that the 2000 English emigrant children now resident in Canada are generally doing well, and that only in rare instances is the desire expressed for return to their native land. In this connexion an extract is inserted from the report of Mr. F. G. A. Butler, chairman of the Emigrant's Information Office, respecting his inspectorial visit to Canada in 1909. Commenting on this document, Mr. Burns remarks that "Mr. Butler's references to the high appreciation shown by the Canadian authorities of the work of the guardians in the emigration of children, and of the value to Canada of the children so emigrated, afford us (the Local Government Board) much satisfaction."

Medical Relief.

Of the total sum expended annually on Poor-law relief about one-fifteenth part is accounted for under the head of "medical relief." Some idea of the extent to which institutional treatment is accepted by the indigent poor may be gathered from the fact that on Jan. 1st, 1911, nearly 34 per cent. of the aggregate of indoor paupers were provided for in Poor-law infirmaries or hospitals. Compared with earlier years much greater attention is now given by guardians to the perfecting of arrangements for nursing sick paupers both in infirmaries and at their own homes; and the number of nurses employed in Poor-law institutions has risen from 4106 in the year 1897 to 7277 in the year last ended. This large accession to the nursing staffs has been due to general improvements in the service rather than to the numerical increase of patients. In only a few instances are nurses employed for exclusive attendance on paupers at their homes; on the contrary, the Board encourages the guardians to subscribe to nursing institutions, and this practice is now annually becoming more general throughout the country.

Care of the Insane; Training of Idiots.

The total number of paupers classed as insane was 118,864, of whom 53,318 were men, 63,160 women, and 2386 children. Of this total, 94,985 were supported in county and borough asylums, 7041 in imbecile asylums, and 12,117 in workhouses—the remaining 4721 being included among outdoor paupers. The average daily number of imbeciles under the care of the managers of the Metropolitan Asylums Board was 6843, of whom 38 were children under 5 years of age. Of the remainder, 212 were over 70 years old, and of these no fewer than six had passed their ninetieth birthday. During the year a certain number of idiots were removed from workhouses and placed in separate institutions provided for the special care and training of idiots, or in institutions registered under the Act of 1886 for the reception of idiots and imbeciles.

[1] Fortieth Annual Report of the Local Government Board, 1910-11, Part I. Wyman and Sons. Price 1s. 2d.

Work of the Metropolitan Asylums Board.

For the classification and treatment of mentally defective children the managers of this Board are at present considering an improved scheme. The number of such children under their care at the end of the year was 331, including a number received in childhood but since passed into adolescence. By the conversion of one of the Board's fever hospitals, the "Park" hospital, near Lewisham, the accommodation for sick and debilitated children was substantially increased last year. The total number of children admitted to this hospital or to the institution near Carshalton was 2485. In the board's ophthalmic schools 682 patients were admitted. The admissions to the ringworm school were 1019, the average duration of treatment there being 3·7 months per case. The Board's seaside homes provided a temporary residence for 942 children in the course of the year.

Maternity Department.

Particulars are given respecting 4493 mothers who were admitted to the maternity wards in the course of the year, showing that the number who died either in the wards or after discharge to the infirmary sick wards was 39, this number including all deaths, whether or not they were primarily due to childbirth. In many cases the deaths were attributed to causes not primarily due to childbirth. In 19 out of the 39 cases the mother did not come into the hospital until the actual day of delivery, or else she was admitted whilst in labour; and in four other cases the child had been born before admission of the mother. It should further be stated that in a large proportion of the cases the mothers who died were very seriously ill, and in some cases actually moribund, on admission.

The tables accompanying this section of the report show the number and causes of death of infants which occurred in the maternity wards during the first and second weeks of life. From these tables we learn that the percentage of children who died in the maternity wards within the first two weeks of life is higher than in the general population. But this is probably due to pre-natal and maternal conditions entirely unconnected with, and independent of, the character of the administration of the lying-in wards. The character of the parents and the conditions in which they have lived are the dominating factors in determining the death-rate. Thus we find that of the 142 deaths in the first week of life 81 were due to premature birth, 46 to congenital defects, atrophy, &c., and 15 to other causes.

PRINCESS ALICE MEMORIAL HOSPITAL, EASTBOURNE.—The committee of the Princess Alice Memorial Hospital, Eastbourne, at the annual meeting of the governors on Feb. 23rd, recorded with very great regret the retirement of Dr. T. Macqueen, Dr. A. P. Sherwood, and Mr. H. D. Farnell from the medical staff, of which they had been members since the foundation of the hospital nearly 29 years ago. Mr. Farnell was the last retiring member of the original medical staff, and to him and the other retiring members the committee felt that not only the hospital authorities, but the whole town of Eastbourne and its neighbourhood, owed a debt of gratitude which could never be adequately repaid. A vote of thanks was accorded Mr. Farnell, who, in responding, mentioned that of the acting staff originally appointed all were alive to-day with the exception of Dr. Hayman. It was announced at the meeting that it had been decided to give a complimentary dinner to the retiring members of the staff on March 16th, and that the Duke of Devonshire would take the chair. By Mr. Farnell's retirement all the original members of the medical staff of the hospital are now superannuated. A new wing at the hospital, to contain 20 beds, is in the course of erection, and with the addition, if sufficient funds can be raised, of a nurses' home to be built in the hospital grounds, will form the Eastbourne memorial to King Edward VII. When the new wing is completed and in working order additional annual subscriptions to the amount of £1000 will be required, and the committee is appealing for new subscribers. So far as Eastbourne is concerned the committee has not found a withdrawal of subscriptions owing to the Insurance Act, but that owing to an energetic canvass the subscriptions were showing a considerable increase, yet hardly up to expectations.

SEVENTEENTH INTERNATIONAL CONGRESS OF MEDICINE.

A MEETING of the Organisation Committee of this Congress was held on Monday afternoon, Feb. 19th, in the Library of the Royal College of Physicians of London, the President of the Congress and of the College being in the chair. Forty-two members were present.

The minutes of the last meeting, which were published in THE LANCET and *British Medical Journal* of July 22nd, 1911, were confirmed.

It was reported from the Executive Committee—(1) that H.R.H. Prince Arthur of Connaught had consented to open the Congress; (2) that certain additional vice-presidents of the Congress and officers of the sections would be elected; (3) that Dr. Clive Rivière, secretary of the Reception Committee, had been elected to the Executive Committee; (4) that the following had been invited to give general addresses: Professor Chauffard in medicine, Professor Harvey Cushing in Surgery, and Geheimrat Professor Paul Ehrlich in pathology, and that they had all accepted; (5) that a circular invitation with lists of sections and principal officers of Congress, rules of Congress, rules of sections, and form of application (published in THE LANCET and the *British Medical Journal* of Jan. 6th, 1912) had been issued by post to 6600 medical men throughout the world, and that abridged notices had appeared in a large number of foreign medical journals; (6) that at a meeting of officers of sections the following programme of discussions had been drawn up, subject to alterations if necessary;—

PROVISIONAL PROGRAMME OF SUBJECTS FOR DISCUSSION.

Section I.—Anatomy.

1. The Excitatory and Connecting Muscular System of the Heart (jointly with III., 2). 2. The Morphology of the Sympathetic System. 3. The Early Stages of the Human Ovum. 4. Cerebral Localisation and the Precise Significance of Sulci. 5. The Morphology of the Shoulder Girdle.

Section II.—Physiology.

1. Internal Secretions (jointly with VI., 1). 2. Reciprocal Innervation. 3. Endogenous Metabolism of Proteins (jointly with III. (a), 5).

Section III.—General Pathology and Pathological Anatomy.

1. The Pathology of Shock. 2. The Excitatory and Connecting Muscular System of the Heart (jointly with I., 1). 3. Grafting of Normal Tissues as Dependent upon Zoological or Individual Affinity; Autoplastic, Isoplastic, Heteroplastic. 4. The Pathology of Fats and Lipoids. 5. The Effect of Radio-active Substances and Radiations upon Normal and Pathological Tissues.

Subsection (a).—Chemical Pathology.

1. Pathological Conditions due to Defects in Diet. 2. Clinical Applications of Pathological Chemistry. 3. The Chemical Pathology of the Alimentary Tract 4. Cancer (jointly with IV., 3). 5. Endogenous Metabolism of Proteins (jointly with II., 3).

Section IV.—Bacteriology and Immunity.

1. Theories of Immunity and Anaphylaxis. 2. Nature of Virulence. 3. Cancer (jointly with III. (a), 4). 4. Filter Passers. 5. Leprosy and Allied Bacilli.

Section V.—Therapeutics.

1. On the Comparative Value of the Cardiac and Vascular Remedies in Common Use. 2. The Mode of Action and Uses of Remedies for Pain or Sleeplessness. 3. Chemical Toxines and Antitoxines. 4. A Laboratory Meeting. 5 A Discussion upon a subject relating to Balneology or Physio-Therapy.

Section VI.—Medicine.

1. Correlation of Organs of Internal Secretions and their Disturbances (jointly with II., 1). 2. Differentiation of the Chronic Arthrites. 3. The Pathology of Heart Failure. 4. Diabetes. 5. The Clinical Aspects of Hæmolysis.

Section VII.—Surgery.

1. The Operative Treatment of Malignant Disease of the Large Intestine (excluding the rectum). 2. The Treatment of Tumours of the Brain, and the Indications for Operation (jointly with XI., 5). 3. Intrathoracic Surgery. 4. The Treatment of Early Renal and Vesical Tuberculosis (jointly with XIV., 1). 5. The Surgery of the Arterial System.

Subsection (a).—Orthopædics.

1. The Treatment of Spastic Paralyses. 2. The Treatment of Scoliosis. 3. Radiography of Bones and Joints, and its value in Orthopædic Surgery (jointly with XXII., 5). 4. The Treatment of Ankylosis. 5. The Treatment of Tuberculous Joints in Childhood. (To be on a different day from X., 3).

Subsection (b).—Anæsthesia.

1. (*a*) Recent Methods of Producing Analgesia: (1) Intrathecal, (2) Local, and (3) Regional; (*b*) Contrast the immediate and after-effects,

especially Shock, e.g., Intrathecal and Local Analgesia with Inhalational Anæsthesia, with special reference to Psychic Shock. 2. Recent Methods of General Anæsthesia: (*a*) Ether—(i.) Open method, (ii.) Intravascular, (iii.) Intratracheal, (iv.) Nasal, and (v.) Rectal; (*b*) Inhalational Anæsthesia in association with Alkaloidal Bodies—(i.) Nitrous Oxide in Major Surgery, (ii.) Ether, (iii.) Chloroform. 3. Dosimetric Method of Administering: (1) Chloroform and (2) Ether—(*a*) Regulators and (*b*) Mixtures. 4. Post-operative Effects and Toxæmias Associated with Anæsthetics.

Section VIII.—Obstetrics and Gynæcology.

1. Cancer of the Uterus (Body and Cervix); operative technique and results. 2. Röntgen and Radium Therapy in Gynæcology (jointly with XXII., 1). 3. The Treatment of Hæmorrhage from the Placental Site (placenta prævia and accidental hæmorrhage) in the later months of pregnancy. 4. Infant Mortality in the First Four Weeks of Life (jointly with X., 5, and XVIII., 1).

Section IX.—Ophthalmology.

1. The Pathogenesis of Chronic Uveitis, excluding the Syphilitic, Tuberculous, and Sympathetic Varieties. 2. Glaucoma Operations, with Special Reference to the Comparative Results attained by Iridectomy and its Recent Substitutes. 3. Affections of the Eye produced by Undue Exposure to Light. 4. Anaphylaxis in its Relation to Ophthalmology. 5. "Demonstration" Meeting or a Discussion upon a Subject not yet Determined.

Section X.—Diseases of Children.

1. Infection of the Urinary Tract with Colon Bacilli (on a different day from XIV., 3). 2. Effects of the Ductless Glands on Development (on a different day from II., 1, and VI., 1). 3. The Treatment of Tuberculosis in Childhood from the Surgical Point of View, with Special Reference to the Bones, Joints, and Glands (on a different day from VII. (*a*), 5). 4. Polio-encephalitis and Poliomyelitis. 5. Infant Mortality in the First Four Weeks of Life (jointly with VIII., 4, and XVIII., 1).

Section XI.—Neuropathology.

1. The Symptoms of Cerebellar Disease and their Significance. 2. Motor Aphasia, Anarthria, and Apraxia. 3. The Relation of Trauma to Degenerative Diseases of the Nervous System. 4. The Nature of the Condition termed Parasyphilis (on a different day from XII., 5). 5. The Treatment of Tumours of the Brain, and the Indications for Operation (jointly with VII., 2).

Section XII.—Psychiatry.

1. The Psychiatric Clinique, its Aims (educational and therapeutic) and the Results obtained in respect to Promotion of Recovery. 2. The Psychoses of Infection and Auto-intoxication. 3. Psycho-analysis. 4. The Psychology of Crime (jointly with XIX., 4), 5. The Syphilitic and the Parasyphilitic Insanities (on a different day from XI., 4).

Section XIII.—Dermatology and Syphilography.

1. Epithelioma of the Skin, Benign and Malignant. 2. Syphilis: its Dangers to the Community, and the Question of State Control (jointly with XIX., 3). 3. Alopecia Areata and Allied Conditions. 4. The Treatment of Syphilis by Salvarsan and Allied Substances (jointly with XX., 7). 5. The Vaccine Treatment of the Diseases of the Skin.

Section XIV.—Urology.

1. The Treatment of Early Renal and Vesical Tuberculosis (jointly with VII., 4). 2. The Early Diagnosis and Treatment of Malignant Disease of the Prostate. 3 The Value of Vaccines in the Treatment of Hæmic Infections of the Urinary Tract.

Section XV.—Rhinology and Laryngology.

1. The Disorders and Pathological Changes produced in the Pharynx and Larynx by the Over-use and Mis-use of the Voice. 2. The Treatment of Syphilitic Diseases of the Throat, Nose, and Ear, by Salvarsan and other Arsenical Compounds (jointly with XVI., 2). 3. The Question of Treatment of Diseases of the Throat and Nose by Therapeutic Inoculation, exclusive of Tuberculin and Diphtheritic Antitoxin. 4. The Special Treatment of the Throat, Nose, and Ear, during the Active Stages of Certain Infectious Fevers—namely, scarlet fever, measles, German measles, mumps, influenza, typhoid, whooping-cough, small-pox, cerebro-spinal meningitis, erysipelas (diphtheria excluded) (combined with XVI., 4). 5. Malignant Disease of the Post-cricoid Region.

Section XVI.—Otology.

1. Pathology of Deaf-Mutism. 2. The Treatment of Syphilitic Diseases of the Throat, Nose, and Ear by Salvarsan and other Arsenical Compounds (jointly with XV., 2). 3. Treatment of Non-suppurative Diseases of the Labyrinth. 4. The Special Treatment of the Throat, Nose, and Ear during the Active Stages of certain Infectious Fevers—namely, scarlet fever, measles, German measles, mumps, influenza, typhoid, whooping-cough, small-pox, cerebro-spinal meningitis, erysipelas (diphtheria excluded) (jointly with XV., 4). 5. Climatic and Occupational Influences in Diseases of the Ear.

Section XVII.—Stomatology.

1. The Pathology and Treatment of Periodontal Disease (Pyorrhœa Alveolaris). 2. The Relation of Nasal Obstruction to Dental Disease. 3. A Discussion on Reflex and Functional Disturbances in Connexion with Teeth. 4. Dental Diseases in Relation to Public Health. 5. The Supervision of the Health of Children between Infancy and School Age (jointly with XVIII., 3).

Section XVIII.—Hygiene and Preventive Medicine.

1. Infant Mortality in the First Four Weeks of Life (jointly with VIII., 4 and X., 5). 2. The Causes, Prevention, and Treatment of Visual Defects in School Children. 3. The Supervision of the Health of Children between Infancy and School Age (jointly with XVII., 5). 4. (*a*) The Factors that Determine the Rise, Spread, and Degree of Severity of Epidemic Diseases; (*b*) Protective Inoculation in Acute Infectious Diseases. 5. The Effects of Dust in producing Diseases of the Lungs.

Section XIX.—Forensic Medicine.

1. The Cause and Prevention of Suicide. 2. The Habitual Inebriate in Relation to Civil and Criminal Responsibility. 3. Syphilis: its Dangers to the Community and the Question of State Control (jointly with XIII., 2). 4. The Psychology of Crime (jointly with XII., 4). 5. The Constitution and Equipment of a Medico-legal Institute.

Section XX.—Naval and Military Medicine.

1. Hospital Ships and Transport of Wounded. 2. Caisson Disease. 3. The Physiology of Physical Training and Marching. 4. Water-supplies in the Field. 5. Antityphoid Inoculation. 6. Transport of Wounded in Hill Warfare. 7. The Treatment of Syphilis by Salvarsan and Allied Substances (jointly with XIII., 4). 8. Sanitary Organisation in the Tropics (jointly with XXI., 5).

Section XXI.—Tropical Medicine and Hygiene.

1. Relapsing Fevers. 2. Leishmaniasis. 3. Plague. 4. Beri-beri. 5. Sanitary Organisation in the Tropics (jointly with Section XX., 8).

Section XXII.—Radiology.

1. Roentgen and Radium Therapy in Gynæcology (jointly with VIII., 2). 2. The Radiotherapy of Malignant Disease. 3. The X Ray Examination of the Chest. 4. The X Ray Examination of the Abdomen. 5. The X Ray Examination of Bones and Joints and its Value in Orthopædic Surgery (jointly with VII. (*a*), 3).

The Executive Committee reported further:—

7. That the following estimate of expenses had been drawn up by the treasurer, reported by the Finance Committee, and adopted:—

ESTIMATE.

I.—General expenditure—	
(*a*) General meetings ... ... (If the Albert Hall be used the expense may be somewhat less)	£300
(*b*) Sectional meetings	800
(*c*) Badge	180
(*d*) Secretarial work	500
Rent of offices	350
(*e*) Printing, postage, stationery, and various	3,250
(*f*) Pathological museum	500
	£5,880
II.—Entertainments—	
1. An opening evening reception.	
2. An evening garden fête or soirée ...	£1,500
III.—Transactions	£5,000
Estimated total expenditure ...	£12,380

8. That on report of the Reception Committee it was resolved to recommend that there be a formal reception by the President on the evening of Wednesday, August 6th, 1913, being the first day of Congress, and that the arrangements for sectional dinners be left in the hands of the sections.

9. That letters having been received from Professor Sudhoff (Berlin) (in the name of the Deutsche Gesellschaft für Geschichte der Medizin), Dr. Comrie (Lecturer on the History of Medicine at Edinburgh), Dr. T. von Györy (Budapest), Dr. E Wickersheimer (in the name of the Société Française d'Histoire de la Médecine), and others, urging the establishment of a section of the History of Medicine, it was resolved to recommend that the establishment of a section of the History of Medicine be recommended to the Permanent Commission.

The report of the Executive Committee was adopted. It was further resolved that the Historic Exhibits Committee be dissolved.

TAVISTOCK (DEVON) COTTAGE HOSPITAL.—At the annual meeting of the subscribers to this hospital, held recently, the chairman referred with regret to the death of Mr. J. Snowden-Smith, who had been a member of the honorary medical staff for the past 19 years. The following were elected honorary medical officers to the institution: Mr. Charles Cumberland Brodrick, L.R.C.P. & S. Edin.; Mr. Albert Bowhay, M.D. Durh., L.R.C.P. Lond., M.R.C.S. Eng., L.S.A., D.P.H. Camb.; Mr. Henry Warren Cowe, M.D., B.Ch. Oxon., L.R.C.P. Lond., M.R.C.S. Eng.; Mr. George Hewlett Stanhope Hillyar, L.R.C.P. & S. Edin., L.F.P.S. Glasg.; and Mr. Charles William Seccombe, L.R.C.P. Lond., M.R.C.S. Eng.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 94 largest English towns having an estimated population of 17,559,219 persons in the middle of this year, 8458 births and 5645 deaths were registered during the week ending Feb. 24th. The annual rate of mortality in these towns, which had been 18·6, 21·6, and 18·6 per 1000 in the three preceding weeks, further declined to 16·8 per 1000 in the week under notice. During the first eight weeks of the current quarter the mean annual death-rate in these large towns averaged 17·2 per 1000, while in London during the same period the average annual death-rate did not exceed 16·4 per 1000. The annual death-rates last week in the several towns ranged from 6·9 in Ilford, 7·8 in Southend-on-Sea, 8·1 in Enfield, 8·3 in Wimbledon, and 8·8 in Ealing, to 24 9 in Salford, 26·5 in West Bromwich, 27·0 in Walsall, 27·4 in Dudley, and 31·4 in Great Yarmouth.

The 5645 deaths from all causes in the 94 towns were 625 fewer than the number in the previous week, and included 353 which were referred to the principal epidemic diseases, against 435 and 365 in the two preceding weeks. These 353 deaths from the principal epidemic diseases included 147 from whooping-cough, 88 from measles, 44 from diphtheria, 39 from infantile diarrhœal diseases, 18 from enteric fever, and 17 from scarlet fever, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 1 0 per 1000, against 1·3 and 1·1 in the two preceding weeks. The deaths attributed to whooping-cough, which had been 166, 186, and 148 in the three preceding weeks, numbered 147 last week, and caused the highest annual death-rates of 1·6 in Edmonton and in Birkenhead, 2·3 in West Bromwich, 3·4 in Walsall, 4·6 in Great Yarmouth, and 5·1 in Merthyr Tydfil. The deaths referred to measles, which had been 63, 98, and 69 in the three previous weeks, increased to 88 last week; the highest annual death-rates from this cause were 1·6 in Nottingham, 1·7 Rhondda, 1·9 in Oxford, 2·1 in Warrington, 2 2 in Salford, and 3·0 in Wakefield. The fatal cases of diphtheria, which had declined from 71 to 43, in the three preceding weeks, were 44 last week, and included 14 in London and its suburban districts, 4 in Leeds, and 3 in Bradford. The deaths attributed to infantile diarrhœal diseases, which had been 67, 49, and 58 in the three preceding weeks, declined to 39 last week; 8 deaths were registered in London and 6 in Manchester. The deaths referred to enteric fever last week numbered 18, and were equal to the average in the seven preceding weeks; 3 deaths were recorded in London and 2 in Bristol. The fatal cases of scarlet fever, which had increased from 21 to 28 in the three preceding weeks, declined to 17 last week, and included 4 in Liverpool and 2 in Leeds.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had been 1500, 1512, and 1461 in the three preceding weeks, had further declined to 1427 on Saturday last; 181 new cases of this disease were admitted to these institutions during the week, against 169, 178, and 154 in the three preceding weeks. These hospitals also contained on Saturday last 1168 cases of diphtheria, 431 of whooping-cough, 212 of measles, 66 of enteric fever, and 2 of small-pox. The 1334 deaths from all causes recorded in London were 231 fewer than the number in the previous week, and were equal to an annual death-rate of 15·4 per 1000. The deaths referred to diseases of the respiratory system, which had been 394, 545, and 440 in the three preceding weeks, further declined to 352 last week, and were 43 below the number recorded in the corresponding week of last year.

Of the 5645 deaths in the 94 large towns, 174 resulted from different forms of violence, and 383 were the subject of coroners' inquests. The causes of 40, or 0·7 per cent., of the deaths registered last week were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Sheffield, Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, Portsmouth, and in 67 other smaller towns. The 40 uncertified causes of death last week included 8 in Birmingham, 8 in Liverpool, 3 in Southport, 3 in Rotherham, 2 in Darlington, and 2 in Gateshead.

HEALTH OF SCOTCH TOWNS.

In the 18 largest Scotch towns, having an estimated population of 2,182,400 persons in the middle of this year, 1102 births and 775 deaths were registered during the week ending Feb. 24th. The annual rate of mortality in these towns, which had been 22·8 and 22·1 per 1000 in the two preceding weeks, further declined to 18·5 per 1000 in the week under notice. During the first eight weeks of the current quarter the mean annual rate of mortality in these towns averaged 19·1 per 1000, and was 1·9 per 1000 in excess of the mean rate recorded during the same period in the 94 large English towns. The annual death-rates in the several Scotch towns last week ranged from 6·1 in Falkirk, 8·8 in Motherwell, and 10·6 in Partick, to 22·7 in Paisley, 23·3 in Ayr, and 23·4 in Greenock.

The 775 deaths from all causes were 148 fewer than the number in the preceding week, and included 120 which were referred to the principal epidemic diseases, against numbers increasing from 89 to 103 in the four preceding weeks. Of these 120 deaths, 62 resulted from measles, 22 from diphtheria, 18 from whooping-cough, 11 from infantile diarrhœal diseases, 4 from enteric fever, and 3 from scarlet fever, but not one from small-pox. These 120 deaths from the principal epidemic diseases were equal to an annual death-rate of 2·9 per 1000, or 1·9 per 1000 above that recorded in the 94 large English towns. The deaths attributed to measles, which had increased from 39 to 63 in the four preceding weeks, were 62 last week, and included 41 in Glasgow, 5 in Greenock, 4 in Edinburgh, 3 in Aberdeen, and 3 in Kilmarnock. The deaths referred to diphtheria, which had been 12, 13, and 6 in the three preceding weeks, rose to 22 last week; 10 deaths were registered in Glasgow, 3 in Leith, 2 in Edinburgh, and 2 in Coatbridge. The fatal cases of whooping-cough, which had been 14 in each of the three preceding weeks, rose to 18 last week, and included 5 in Ayr and 4 in Glasgow. The deaths of infants attributed to diarrhœal diseases, which had been 6 and 14 in the two previous weeks, declined to 11 last week, of which number 4 were recorded in Glasgow. The 4 deaths referred to enteric fever were equal to the number in the previous week, and included 2 in Glasgow. The 3 fatal cases of scarlet fever were registered in Glasgow, Edinburgh, and Aberdeen respectively.

The deaths referred to diseases of the respiratory system, which had been 220 and 209 in the two previous weeks, further declined to 192 last week; and 19 deaths were attributed to different forms of violence.

HEALTH OF IRISH TOWNS.

In the 22 town districts of Ireland, having an estimated population of 1,157,014 persons in the middle of this year, 566 births and 545 deaths were registered during the week ending Feb. 24th. The annual rate of mortality in these towns, which had been 31·0 and 26·6 per 1000 in the two preceding weeks, further declined to 24 6 per 1000 in the week under notice. During the first eight weeks of the current quarter the mean annual death-rate in these Irish towns averaged 23·7 per 1000; in the 94 large English towns the mean annual death-rate during the same period did not exceed 17·2 per 1000, while in the 18 Scotch towns it was equal to 19·1 per 1000. The annual death-rates in the several Irish towns last week were equal to 23 3 in Dublin (against 15·4 in London), 26 9 in Belfast, 24 5 in Cork, 12·7 in Londonderry, 23·1 in Limerick, and 38·0 in Waterford; while in the 16 smallest of these towns the death-rate last week was equal to 23·1 per 1000.

The 545 deaths from all causes in the 22 Irish towns were 45 fewer than the number in the previous week, and included 27 which were referred to the principal epidemic diseases, against 49 and 42 in the two preceding weeks; of these 27 deaths, 14 resulted from whooping-cough, 5 from infantile diarrhœal diseases, 3 from measles, 2 from scarlet fever, 2 from diphtheria, and 1 from enteric fever, but not one from small-pox. These 27 deaths from the principal epidemic diseases were equal to an annual death-rate of 1·2 per 1000; the death-rate last week from these diseases did not exceed 1·0 per 1000 in the 94 large English towns, while in the 18 Scotch towns it was equal to 2 9. The deaths attributed to whooping-cough, which had been 25 and 21 in the two preceding weeks, further declined to 14 last week, and included 9 in Belfast and 4 in Dublin.

The deaths of infants referred to diarrhœal diseases numbered 5 last week, against 7 and 8 in the two preceding weeks; 2 deaths were recorded in Dublin. The fatal cases of measles, which had increased from 2 to 8 in the three preceding weeks, declined to 3 last week, and comprised 2 in Dublin and 1 in Clonmel. The 2 deaths from scarlet fever, the fatal case of enteric fever, and 1 of the 2 deaths from diphtheria were registered in Dublin.

The deaths referred to diseases of the respiratory system, which had been 239 and 212 in the two preceding weeks, further declined to 189 last week. Of the 545 deaths from all causes in the 22 Irish towns, 129, or 24 per cent., occurred in public institutions, and 5 resulted from different forms of violence. The causes of 29, or 5·3 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 94 large English towns the proportion of uncertified deaths in the week under notice did not exceed 0·7 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

Surgeon Arthur Robertson Davidson has been promoted to the rank of Staff-Surgeon in His Majesty's Fleet (dated Feb. 23rd, 1912).

The following appointments have been notified:—Deputy Surgeons-General: W. H. Norman to Malta Hospital; D. T. Hoskyn to Hong-Kong Hospital; E. R. Dimsey, D.S.O., to Haslar Hospital; W. W. Prym to Chatham Hospital; and P. B. Handyside to Plymouth Hospital. Fleet-Surgeons: M. L. B. Rodd to the *President*, additional, for three months' special course in surgery at the Dreadnought Seamen's Hospital; R. A. Ross to the *Hindustan*, on recommissioning; W. E. Marshall to the *Duke of Edinburgh*, on recommissioning; and E. A. Penfold to the *Excellent*, additional, for the *Revenge*. Staff-Surgeons: F. Bolster to Plymouth Hospital, temporary; R. W. G. Stewart to the *Racer*, additional, for Osborne College, temporary; C. R. Sheward to the *Pomone*, additional, for Royal Naval College, Dartmouth; G. H. S. Milln to the *Duke of Edinburgh*, on recommissioning; and H. C. Whiteside to the *St. George*, temporarily. Surgeon: F. G. H. R. Black to the *Hecla*.

ROYAL ARMY MEDICAL CORPS.

The undermentioned Lieutenants to be Captains (dated Feb. 1st, 1912):—Charlie Ryles, David S. Buist, William E. Marshall, Alexander M. Pollard, Gilbert G. Collet, Colin Clarke, Edmund V. Vaughan, Arthur N. R. McNeill, Andrew R. Wright, Thomas B. Nicholls, Julian B. Jones, James A. Clark, Stuart McK. Saunders, Thomas J. Mitchell, Frank H. Somers-Gardner, Donald H. C. MacArthur, George S. Parkinson, Herbert Gall, Charles H. O'Rorke, Austin W. Byrne, John Startin, Charles G. Sherlock, George H. Stack, Harold H. Leeson, Samuel W. Kyle, John W. Lane, William G. Wright, and Albert T. J. McCreery.

The undermentioned to be Lieutenants (on probation) (dated Jan. 26th, 1912):—Alexander Gordon Biggam, Lieutenant David Torquil Macleod Large (from the Royal Army Medical Corps, Special Reserve), William Francis Christie, Roy Kyffin Mallam, Walter Woodall Pratt, Walter Stevenson, Maurice Burnett, Cuthbert James Blaikie, James Hebblethwaite Martin Frobisher, Christopher Martin Ingoldby, Owen Waller James Wynne, Lieutenant David Turnbull Richardson (from the Royal Army Medical Corps, Special Reserve), Edward Alexander Strachan, Lieutenant William McNaughtan (from the Forth Royal Garrison Artillery, Territorial Force), Lieutenant Sydney James Higgins (from the Royal Army Medical Corps, Special Reserve), Alexander Hood, John Lichtenstein Ritchie, Gilbert Alan Blake, Henry Roland L'Estrange, Cuthbert Joseph Harwood Little, Percy Arthur With, Robert Washington Vint, Stephen James Barry, Harold Wordsworth Leach Allott, and Edward Percival Allman Smith.

The undermentioned Lieutenants (on probation) are seconded under the provisions of Article 300, Royal Warrant for Pay and Promotion, 1909 (dated Jan. 26th, 1912):—Alexander G. Biggam, Walter W. Pratt, Maurice Burnett, Gilbert A. Blake, Cuthbert J. H. Little, Robert W. Vint, Harold W. L. Allott, and Edward P. A Smith.

Surgeon-General H. R. Whitehead, principal medical officer of the Southern Command at Salisbury, has been selected for appointment as Principal Medical Officer of the Eastern Command, with effect from March 20th, on the retirement of Surgeon-General J. C. Dorman, C.M.G., honorary physician to His Majesty the King. Colonel A. F. Russell, C.M.G., lately commanding the Station Hospital at Malta, has taken up duty as Principal Medical Officer at Cairo, in succession to Colonel T. M. Corker, promoted Surgeon-General and transferred to the Indian Establishment. Colonel H. J. Barratt, lately senior medical officer in the Straits Settlements, has taken up duty as Principal Medical Officer of the Allahabad Brigade in India.

Lieutenant-Colonel F. W. Caton Jones, commanding the Station Hospital at Quetta, has been selected to succeed Lieutenant-Colonel E. H. L. Lynden Bell in the command of the Station Hospital at Meerut Cantonment. Lieutenant-Colonel A. L. F. Bate, on arrival home from India tour expired, has been posted to the Western Command. Lieutenant-Colonel F. P. Nichols, on relinquishing charge of the Military Hospital at Jersey, has taken up duty at Bodmin. Lieutenant-Colonel W. L. Gray, on arrival in India for a tour of duty, has been selected to command the Station Hospital at Jullundur. Lieutenant-Colonel R. L. R. Macleod, on return from a tour of service at Aden, has taken over charge of the Military Hospital at Devonport. Lieutenant-Colonel H. C. Thurston has been transferred from the Aldershot Command to the Royal Military Hospital at Sandhurst as Senior Medical Officer, vice Lieutenant-Colonel C. C. Reilly, whose tenure of the appointment has expired. Lieutenant-Colonel J. W. Bullen, lately commanding the Station Hospital at Wellington, Madras Presidency, has been selected to command the Station Hospital at Maymyo, Burma, in succession to Lieutenant Colonel C. E. Nichol, D.S.O., appointed Principal Medical Officer of the Presidency and Assam Brigades.

An exchange on the roster of foreign service has been sanctioned by the War Office between Major F. W. Begbie, serving at Colchester, and Major E. T. F. Birrell, Deputy Assistant Director-General, Army Medical Service. Major N. Faichnie, specialist sanitary officer, Fifth (Mhow) Division, has been granted eight months' general leave of absence in India. Major E. E. Powell, from Bordon, has taken up duty at Aldershot. Major A. J. MacDougall, on return from a tour of duty in Ceylon, has been posted to the Irish Command. Major F. S. Irvine has been transferred from the Aldershot Command to the Royal Army Medical College. Major C. F. Wanhill, Assistant Professor of Hygiene at the Royal Army Medical College, on arrival in India will be posted to the Fifth (Mhow) Division. Major J. D. G. Macpherson, in charge of the Military and Cantonment Hospitals at Pachmarhi, has been granted eight months' general leave of absence home from India with effect from March 18th. Major W. H. S. Nickerson, V.C., has been transferred from Peshawar to the Station Hospital at Rawal Pindi.

Captain M. B. H. Ritchie, Officiating Staff Officer of Medical Mobilisation Stores in the Second (Rawal Pindi) Division, has been granted one year's extension of his tour of service in India by His Excellency the Commander-in-Chief. Captain T. S. Blackwell, commanding the Station Hospital at Bhamo, has been detailed for duty on board the troopship s.s. *Rohilla*, which left Karachi for Southampton on Jan. 31st. Captain R. E. Humfrey, on return from duty at the Station Hospital, Jhansi, has been ordered to join in Ireland on April 2nd, and on arrival will be posted to the Dublin District. Captain W. Benson, lately holding charge of the Cantonment General Hospital at Rawal Pindi, has been directed to join in Ireland on March 2nd, and will be posted for duty to the Dublin District. Captain C. G. Browne, specialist in dermatology and venereal diseases to the Eighth (Lucknow) Division, has been granted six months' leave of absence home from Feb. 15th. Captain R. F. Ellery, from Benares, has taken up duty at the Station Hospital at Bareilly. Captain B. H. V. Dunbar has been moved from Enniskillen to Belfast for duty at the Military Hospital. Captain A. W. Sampey has left the Military Hospital at Warley for a tour of service in India with the Seventh (Meerut) Division. Captain R. H. MacNichol has taken up duty at the Royal Herbert Hospital, Woolwich, as Specialist in Dermatology and Venereal Diseases.

The following Lieutenants have been appointed for duty in

the Southern Command:—F. S. Tamplin, J. M. Elliott, and A. S. Heale. Lieutenant S. S. Dykes, from Aberdeen, has taken up duty at Piershill. Lieutenant P. S. Tomlinson has been transferred from Bulford Camp to the Military Hospital at Tidworth. Lieutenant E. C. Stoney has, on arrival in India, been appointed for duty in the Ninth (Secunderabad) Division of the Southern Army.

INDIAN MEDICAL SERVICE.

The Honourable Surgeon-General Sir C. P. Lukis, K.C.S.I., Director-General of the Indian Medical Service, has been appointed a Knight of Grace of the Order of St. John of Jerusalem in England. Brevet-Colonel H. F. Cleveland, principal medical officer of the Aden Brigade, has been granted leave of absence home. Lieutenant-Colonel A. O. Evans has been appointed to officiate as Principal Medical Officer of the Kohat Brigade. Lieutenant-Colonel J. Chaytor-White, Bengal Presidency, has been granted three months' extension of his leave of absence by the Right Honourable the Secretary of State for India, on the recommendation of a medical board. Lieutenant-Colonel J. B. Smith, civil surgeon at Poona, has arrived home on one year's leave of absence from Bombay.

His Excellency the Governor of Bombay in Council has been pleased to appoint Major E. C. G. Maddock on return to duty from leave, to be Civil Surgeon at Ahmednagar. Major J. W. Cornwall has been granted two years and seven months' leave of absence home from India. Major E. M. Ellington has been selected for appointment as District Medical Officer at Vizagapatam. Major E. F. G. Tucker has been appointed to officiate as Police Surgeon at Bombay. The services of Major S. A. Harris have been placed at the disposal of the Government of the United Provinces of Oudh and Rohilkhund. Major A. E. Walter, superintendent of the X Ray Institute at Dehra Dun, has been awarded the Kaiser-i-Hind gold medal. Major C. C. Murison, superintendent of the Matheran Lunatic Asylum at Colaba, has been appointed a Magistrate for the Bombay District. Major C. B. Prall has arrived home on leave of absence from Bengal Presidency.

Captain K. S. Singh, plague medical officer at Karnal, has been transferred to Amritsar. Captain T. T. Thompson has arrived home on leave of absence. Captain H. C. Keates has passed the colloquial examination in Punjabi and has been confirmed as a Civil Surgeon. Captain C. A. Gill has been appointed to officiate as Civil Surgeon at Simla during the absence on leave of Lieutenant-Colonel C. Duer. Captain A. Cameron, plague medical officer at Delhi, has been transferred to Gurdaspur. Captain J. Husband has been appointed a Specialist in Advanced Operative Surgery. Captain N. S. Sodhi, plague medical officer at Gurgeon, has been transferred to Ludhiana.

TERRITORIAL FORCE.

Royal Army Medical Corps.

3rd West Lancashire Field Ambulance, Royal Army Medical Corps: Mitchell Innes Dick to be Lieutenant (dated Dec. 15th, 1911).

DEATHS IN THE SERVICES.

Inspector-General Edward Elphinstone, C.B., R.N. (retired), at his residence, Holland Park-avenue, on Feb. 26th. He entered the service in 1878, took part in the first Boer war, landing with the Naval Brigade, and was present at Laing's Nek and at Majuba (mentioned in despatches and specially promoted to staff-surgeon). He also served in Egypt and landed with the army during the Burma war of 1885–87.

EXETER DISPENSARY.—The annual meeting of the subscribers to this institution was held recently, under the presidency of the Mayor (Dr. C. J. Vlieland). The financial statement showed that at the end of 1911 an adverse balance of £101 remained. The medical report stated that during the year 4918 patients had been treated, against 5068 in 1910. It was reported that the medical staff, considering the amount of visiting delegated to the visiting medical officer to be excessive, had suggested that two members of the staff should perform the duties and that an honorarium of 40 guineas each should be awarded them. A resolution to that effect was adopted. Dr. Henry Davy was elected president for the ensuing year.

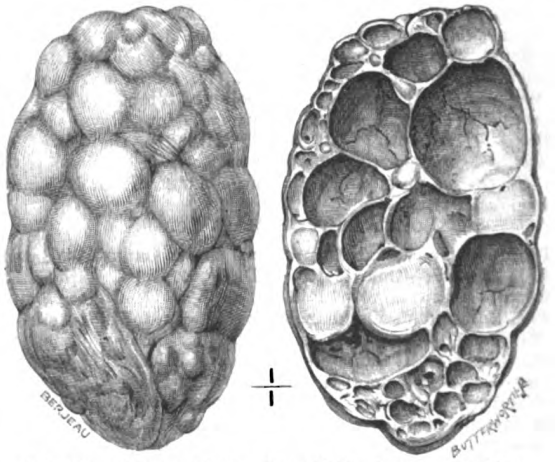
"Audi alteram partem."

THE "RADICAL" OPERATION FOR MALIGNANT DISEASE OF THE TESTICLE.

To the Editor of THE LANCET.

SIR,—In his comment on Mr. H. Morriston Davies's contribution entitled "Malignant Disease of the Testicle and the Treatment of it by Operation," Sir Alfred Pearce Gould asks in THE LANCET of Feb. 24th for information concerning the subsequent history of the patients who have been submitted to this operation. I am able to supply some. At the date on which you published my account of "An Improved Method of Removing the Testicle and Spermatic Cord for Malignant Disease"[1] I had no knowledge that a similar operation had been performed several times in France. In 1911 Dr. Paul Calin, of Lyons, sent me a copy of his admirable brochure, "Du Traitement Chirurgical du Cancer du Testicule (Extirpation des Ganglions Ilio-lombaires)," containing descriptions of 15 cases in which this radical operation had been attempted or performed. He includes my case in the series, and has been able to ascertain the after-history of some of the patients.

This "radical," or, as I prefer to call it, improved, method of removing the testicle for malignant disease, has been performed 17 times. In three instances with fatal results (Morestin, Michel, Gayet). Grégoire attempted it on three occasions. In the first operation (1905) he removed the



A lymph node removed from beneath the sternal end of the left sterno-mastoid muscle. From a man whose right testicle had been removed for cystic disease six months previously. (From "Tumours, Innocent and Malignant," fifth edition.)

testicle, but the gland mass in the abdomen was irremoveable and one gland was excised for examination. The patient survived the castration two and a half years. Grégoire's second operation took place in 1907. Extirpation of the gland mass was impossible. The man recovered from the operation, but returned to the hospital two months later with ascites and the "membres inférieurs gonflés d'œdéme donnant l'impression de membres d'éléphants." He died a few months later. His third was in 1908; the patient survived it six months and succumbed with secondary deposits in the lungs. Fredet found a lymph gland on the aorta of his patient so firmly adherent that it could not be removed. He recovered from the operation; a few months later it was possible to make out by palpation a hard pre-vertebral mass in the region of the irremoveable gland. These results are not encouraging. Cuneo's patient could not be traced; he was an Italian, and after the operation returned to his own country. Gosset's patient was seen ten months after the

[1] THE LANCET, Nov. 13th, 1909, p. 1406.

operation in good health and free from obvious signs of recurrence.

In my case the subsequent history is of interest. The operation was performed on Sept. 8th, 1909, for cystic disease. The testicle and spermatic cord, with the vessels and lymphatics, were removed in one piece. The vena cava and aorta were exposed as high as the transverse portion of the duodenum. The only lymph gland I could find rested on the inferior vena cava; it was as big as a bean. The parts about the aorta were examined with eyes and fingers very thoroughly. Six months after the operation the patient returned with a swelling under the sternal end of the left sterno-mastoid muscle. This I exposed by operation, and shelled out a lymph node as big as a bantam's egg (see figure). This was cystic, and the cysts were lined with epithelium corresponding with that in the cystic spaces of the primary tumour. Two years after the operation the patient reports himself to be in good health. It is astonishing to find a tumour with so low a degree of malignancy as cystic disease of the testicle making use of the thoracic duct to climb up to the lymph nodes at the root of the neck.

The remaining cases are too recent for an opinion to be expressed as to the ultimate value of the operation, but the facts collected by Dr. Calin give a somewhat different complexion to the operation than the inaccurate summary furnished by Mr. Morriston Davies. The operation is worth an extended trial. I agree with Dr. J. K. Jamieson and Mr. J. F. Dobson[2] that the complete removal of the lymphatic area around the mesenteric and renal arteries is impracticable, but I maintain that by operating early we may hope in a proportion of cases to get beyond the infected lymphatics. The improved operation for removing the testicle will not be limited to castration for malignant disease. I have performed it with a good result in tuberculous disease of the testicle.

I am, Sir, yours faithfully,

Brook-street, W., Feb. 26th, 1912. JOHN BLAND-SUTTON.

To the Editor of THE LANCET.

SIR,—Sir Alfred Pearce Gould reproves me for my use of the word "radical" in connexion with the operation for the removal of the testicle together with the lymphatics, fascia, and primary set of glands, and suggests that the results of the 13 cases in which the operation was done do not justify the use of that term. But may I point out to him that the word "radical" was applied to this operation by other authors previous to me, and I conclude that they—as I certainly have done—mean "radical" to denote the anatomical range of the operation as in the current use of the word when applied to certain well-defined operations on the breast and mastoid or for the cure of herniæ, and not to the results.

As regards the actual results, my case has since developed a recurrence, but that has no bearing on the object of my paper, as I cannot suppose that anyone would draw conclusions on the value of an operation for malignant disease from the results of 13 cases only. The cases show that the operation is feasible and not dangerous, and I desire to emphasise the advisability on general principles of a further trial of the major operation in suitable cases so that a sufficient number of records may be collected in order to determine the value of this procedure.

I am, Sir, yours faithfully,

Harley-street, W., Feb. 24th, 1912. H. MORRISTON DAVIES.

THE RECENT OUTBREAK OF POLIOMYELITIS AT STOKE RIVERS.

To the Editor of THE LANCET.

SIR,—In your issues of Feb. 17th and 24th, which contain your criticism of the recent Local Government Board report on the prevalence of acute poliomyelitis in Devon during last summer, you state in regard to the outbreak at Stoke Rivers that among the whole 36 cases there is not a single case of definite poliomyelitis. I should like to point out that Dr. R. J. Reece left the locality before this particular outbreak occurred, and his report was evidently written some time in October, since which date I have kept him posted up in the subsequent course of the epidemic, some further details of which he communicated to the Epidemiological Section of the Royal Society of Medicine in a paper read in January.

At Dr. Reece's particular wish I closely investigated the Stoke Rivers outbreak, and from my personal acquaintance of about 150 cases of the disease, both in company with Dr. Reece and after his departure, I have not the slightest doubt that these at Stoke Rivers were instances of true poliomyelitis. (Thirty were of the abortive type, three of the bulbar or pontine form, two of the spinal poliomyelitis type, and one of the polyneuritic type.) One of the spinal form (paraplegia), taken ill on Oct. 26th, had an abortive attack on Sept. 25th.

I notice in your leading article of Feb. 24th that you lay stress on the point that Dr. Reece attached considerable importance to Kernig's sign. Whilst investigating cases in my presence he certainly only looked upon it, when present, as a sign which indicated implication of the spinal cord, in the same manner as other observers have in different parts of the world. As to the nature of the poison, it is most important, as you suggest, that further research in our own country should be carried out for finding this. I have a strong feeling that the "carrier" plays an important part in the dissemination of the virus; but our knowledge of the etiology and epidemiology of this disease must be materially added to before it is possible to speak definitely as to its method of spread. The reports of the Local Government Board show in what direction experimental research and careful observation of cases should be directed. We do not know whether the disease can be conveyed directly or indirectly by animals, or by animal parasites, or by dust. Is it possible that the virus can exist outside the animal body? Can it survive in milk? Investigation of these points, among others, is urgently required.

I am, Sir, yours faithfully,

GEORGE ADKINS,

Feb. 22nd, 1911. County Medical Officer of Devon.

THE INFECTIVITY OF CANCER.

To the Editor of THE LANCET.

SIR,—I read with interest and appreciation two lectures on "Unicellula Cancri" by [the late] Sir Henry Butlin,[1] who has done good service in once more emphasising the fact that the parasite of cancer is the cancer cell itself, even though it may not be possible absolutely to identify cancer cells with protozoa, as he has suggested.

The question of priority is of less importance than is the fact that this conception of the cancer cell has been reached independently by other workers. In September, 1905, at the Australasian Medical Congress in Adelaide, I gave an address on cancer and tumour-growth, published in the *Australasian Medical Gazette* and in the *Edinburgh Medical and Surgical Journal*, in which I suggested (1) that the relation of the chorionic epithelium to the maternal decidua was essentially that of a neoplasm of restricted malignancy, so far as local infiltration and independence of growth was concerned—the fertilised ovum being for a time definitely parasitic upon the mammalian organism; (2) that the development of cancer was a biological phenomenon *sui generis*, and implied the generation of a new organism; (3) that the cancer process was an invasion of the parent organism by a brood of independent and hostile cells, equivalent to a microbic infection.

Again, in February, 1907, I elaborated these suggestions in an address to the First Australasian Dental Congress, published in the *Australasian Medical Gazette* and in THE LANCET.[2] I then said: "Whereas the cells of the healthy animal body are all working for the common good, the cancer cell appears as a seceder from this commonwealth. ..... Whatever the ultimate nature of cancer may prove to be, this at least is certain, that it constitutes an invasion of the organism by a brood of independent and hostile cells, and that, once these cells have made their appearance within the organism, they may undergo a practically indefinite and unlimited multiplication and proliferation. But these are precisely the conditions that go to make up the process of infection, and so we reach the general conclusion that, in a very definite and intelligible sense, cancer is an infective disease—as certainly infective as any disease due to an invasion of the organism by other parasitic cells, whether of bacterial or of animal origin. ..... Although the existence of a specific

[2] The Lymphatics of the Testicle, THE LANCET, Feb. 19th, 1910, p. 493.

[1] THE LANCET, Nov. 25th (p. 1457) and Dec. 2nd (p. 1535), 1911.
[2] THE LANCET, June 8th, 1907, p. 1564.

cancer parasite is at the best doubtful, the existence of the parasite, cancer, is beyond a doubt. ..... The cancer cell is in itself a parasite, and is endowed with that formidable attribute of the more highly pathogenic parasites—the attribute of infectivity." I then pointed out that, although cancer is an "infective" disease, it is probably not "infectious." I went on to show that a due appreciation of the "infective" nature of cancer tends, not to confuse, but to coördinate certain phenomena of tumour-growth, such as relative malignancy, which otherwise are hard to apprehend.

I am, Sir, yours faithfully,

University of Sydney, Jan. 15th, 1912. D. A. WELSH.

THE CRESCENDO MURMUR OF MITRAL STENOSIS.

To the Editor of THE LANCET.

SIR,—I beg to thank you for your very appreciative and much appreciated review of my small work on the elements of cardiac auscultation which appeared in THE LANCET of Jan. 27th. In this review you say that "the view that the crescendo murmur of mitral stenosis is ventricular systolic and not auricular systolic is, we believe, gradually gaining ground, but it is not as yet generally adopted." May I direct the attention of your readers interested in the subject to a paper by Weiss and Joachim, of Königsberg University, published in the *Zeitschrift für Klinische Medicin*, 1910, Vol. XIII.? These observers have done me the honour of devoting five of the eighteen pages of their article (The Registration of the Heart Sounds and Murmurs by Means of the Phonoscope, and their Relation to the Electro-cardiogram) to testing my theory on the causation of the crescendo murmur. They have taken tracings of the heart sounds and murmurs of mitral stenosis by means of the phonoscope synchronously with tracings of the movements of the auricle and ventricle with the string galvanometer. The evidence thus gained on the point at issue is therefore absolutely reliable. In their paper they say that if my theory is correct two things must happen: (1) The first sound in mitral stenosis must be abnormally delayed; and (2) the commencement of the crescendo murmur must be at a point of time at which the commencement of ventricular systole may be assumed.

These conditions are quite fair. As to the first point, they say that in 17 out of 18 cases of pure mitral stenosis the first sound was definitely late; and as to the second, they conclude that "the terminal portion of the crescendo murmur—namely, that portion which immediately precedes the first heart sound—is of ventricular origin, that is protosystolic." Dr. Joachim in a private letter says that he agrees with my contention as to the causation of this terminal part of the crescendo murmur, which he calls protosystolic in rhythm, and I call early ventricular systolic or presphygmic. I have always limited my argument to that part of the so-called presystolic murmur of mitral stenosis, which is of crescendo force and *rising pitch*, and this only occurs immediately before the first sound by which it is abruptly terminated. Murmurs of increasing force unless accompanied by rising pitch are not the true so-called crescendo murmurs. I may also state that papers by other writers are being published from time to time in which a true crescendo murmur is heard, but there is no evidence of auricular systole—i.e., as judged by electro-cardiograph tracings (e.g., on the Mechanism of the Presystolic Murmur, T. Stuart Hart, *Medical Record*, July 1st, 1911).

I am, Sir, yours faithfully,

E. M. BROCKBANK, M.D. Vict., F.R.C.P. Lond.

Manchester.

THE PATHOLOGY AND TREATMENT OF EXOPHTHALMIC GOITRE.

To the Editor of THE LANCET.

SIR,—I am much interested in Dr. G. R. Murray's paper in THE LANCET of Feb. 24th on the above subject. He mentions a case that had 11 doses of X rays in about five weeks from Nov. 28th, 1911, to Jan. 5th, 1912. The right lobe of the thyroid was removed on Jan. 9th, and he states that now the pulse-rate varies from 92 to 120, whereas, before the operation, it varied from 120 to 204. I would like to suggest that the good result is largely due to the application of the rays rather than to the operation.

Since 1905 I have treated 31 cases of Graves's disease with X rays alone in private and in hospital practice. Of the 14 private cases 10 are cured and the remaining 4 practically well. Of the 17 hospital cases 7 are cured, 4 are markedly relieved, 4 show very little relief, 1 was operated on with a fatal result after five applications, and 1 has only started treatment. Altogether, therefore, the cured and greatly relieved number over 80 per cent. I claim that no other method of treatment, surgical or otherwise, can show such good results in this most intractable of diseases.

Here in Leeds we are coming to the conclusion that the X rays is, so far, the only rational and scientific mode of treatment.

I am also interested in the microscopical findings of the lobe of the thyroid that had been exposed to the rays. If it had been removed later these changes would have been more marked.—I am, Sir, yours faithfully,

LEO. A. ROWDEN, M.B., C.M.,
Honorary Director, Electro-Therapeutic Department,
Feb. 25th, 1912. General Infirmary, Leeds.

WEEKLY PAYMENTS AT ST. BARTHOLOMEW'S HOSPITAL: A CORRECTION.

To the Editor of THE LANCET.

SIR,—Considerable inconvenience has been caused by a statement which appeared in the press on Feb. 22nd, implying that St. Bartholomew's Hospital is offering treatment "for a weekly payment of £2."

I wish to say that no such offer has been made, nor has there at any time been a suggestion of making an offer of the kind. The statement is therefore entirely without foundation so far this hospital is concerned, and I can only assume it was made under a misapprehension.

I am, Sir, yours faithfully,

Feb. 24th, 1912. THOMAS HAYES, Clerk.

UNICELLULA CANCRI.

To the Editor of THE LANCET.

SIR,—I have only recently read the very interesting lectures on Unicellula Cancri delivered by the late Sir Henry Butlin before the Royal College of Surgeons, and reported in THE LANCET of Nov. 25th and Dec. 2nd, 1911. An explanation of the facts put forward occurred to me some three or four years ago. It is that cancer and sarcoma (and also some of the benign growths) are due to, not a symbiotic association of a parasite and a tissue cell, but to a sort of "fertilisation" of a tissue cell by a parasite of a protozoan nature. The result is, as is said in the lectures, that a new "animal" is produced which is similar to the original cell in nature and growth in many respects, and yet, so to speak, has a strange new vitality. As the tissue cell before the process which I call "fertilisation" takes place was a *specialised* cell, so the new growth is a multiplication of that cell, and of that kind of cell only.

The chief facts in support (other than those put forward in the lectures) are three in number. 1. The workers at the Cancer Research Laboratories have shown that the cells in a beginning cancer and in the edge of a growing tumour behave for several generations like germinal cells undergoing maturation, as judged by the karyokinetic figures observed. 2. They have also shown that the blending of "white blood corpuscles" (really, in my opinion, amœboid parasites) with tissue cells can sometimes be observed in very young growths (but I understand *not* in metastases). 3. By other observers working with mice tumours it has now been conclusively proved that sometimes a carcinomatous transplantation has suddenly taken on sarcomatous characters. This last is easily understandable if we assume that under the conditions of the experiment (perhaps simulating the natural conditions suitable to the growth of débris from a naturally sloughing tumour which has naturally become lodged in a susceptible host) the reverse of the "fertilisation" sometimes occurs and the parasite itself is regenerated in a form able to attack any cell handy to it in its new host and by a new "fertilisation" sets up a new type of growth, and, if the cell of the host attacked happens to be a connective tissue cell, a sarcoma results.

According to this view there are possibly two species of parasite. One only endows the cell it fertilises with powers

of multiplying, thus giving rise to "benign" tumours. The second endows the "monstrous hybrid" with the power of dissolving other cells and tissues, and thus these "malignant" growths readily invade contiguous tissues and are able to encroach on lymphatics and blood vessels, and thus form metastases. Combine this idea with the facts put forward in the lectures of Sir Henry Butlin, and we see that it *is* a "new animal," but of such a sort as has only hitherto been foreshadowed in some of the experiments as to the fertilisation of the sperms of the sea-urchin where "fertilisation" of a nature approaching that suggested above has already been achieved experimentally.

I am, Sir, yours faithfully,

R. C. T EVANS, M.B., B.S. Lond.

Herne Bay, Feb. 26th, 1912.

FATALITIES FOLLOWING THE INTRAVENOUS INJECTION OF SALVARSAN.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Feb. 24th you publish a letter bearing the above title from "M.D." In the early months of 1911 we had frequent occasion to reply to similar alarmist reports of fatal accidents following the use of salvarsan. We do not deny that the patients whose cases he quotes all died. We should have been surprised if some of them had survived, for in the first case he mentions the patient was undoubtedly poisoned by a huge overdose of the drug. He received on Sept. 18th an intravenous injection of 60 centigrammes, and, apparently without any investigation to ascertain how much of the first dose he had eliminated, he received another full dose on Sept. 21st. Naturally he died. He was poisoned.

In the Geneva case the necropsy revealed that the patient was suffering from lepto-meningitis, *chronic* bronchitis, and broncho-pneumonia. Why, therefore, throw all the blame of his death on salvarsan? The Amiens case is like the first case quoted, in so far as apparently no trouble was taken to ascertain if the first dose had been eliminated before the second was administered. If strychnine or morphia were administered in full doses, and these full doses were repeated before the patients had eliminated the first doses, disaster would certainly follow. And yet it is admitted that both strychnine and morphia are invaluable drugs. But in their wise administration a little common sense is usually employed. It is a great and deplorable misfortune that in using or criticising the use of salvarsan ordinary intelligence, and in a far greater degree common sense, have been in abeyance in many cases.

We have now had a considerable experience of salvarsan comprising more than a hundred injections, most of which were administered intravenously. We have never had the least occasion for anxiety regarding any one of these patients. In addition, we know of close on 1400 injections which have been administered without accident by our friends. We believe most strongly that a careful technique and the choice of suitable patients will eliminate most of the risks, though we are firmly persuaded that an intravenous injection should never be given single-handed and without the careful preparation of the patient and a thorough examination of his powers of elimination.

In conclusion, we may again affirm that we regard salvarsan as one of the greatest boons conferred on suffering humanity in our time. We are, Sir, yours faithfully,

G. S. STOPFORD-TAYLOR.

Liverpool, Feb. 26th, 1912. R. W. MACKENNA.

THE TREATMENT OF TUBERCULOSIS AND THE SANATORIUM QUESTION.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Feb. 24th, p. 546, you published the names of those gentlemen who had been appointed by the Chancellor of the Exchequer to report at an early date upon the consideration of general policy in respect of the problem of tuberculosis in the United Kingdom, in its preventive, curative, and other aspects, which should guide the Government and local bodies in making or aiding provision for the treatment of tuberculosis in sanatoriums, or other institutions, or otherwise. You refrained, however, from commenting on the constitution of the committee. Will you therefore permit me to offer a few criticisms on the appointments which have been made, such criticism having been founded, not only on my own opinion, but upon the views of several prominent members of the profession with whom I have discussed the matter. No one will dispute the wisdom of the formation of such a committee, but whoever decided upon its composition was not well advised. The reference to the committee is a wide one, and therefore various schools of thought ought to have been represented, instead of which every member of the committee is known beforehand to be pledged to support the sanatorium movement. This fact alone must serve to weaken any recommendations which the committee may arrive at. Further, there are some remarkable omissions; there is no physician on the committee who is a consulting physician to or on the senior acting staff of one of the special hospitals for diseases of the chest in London. As Mr. Clement Lucas has pointed out in the *Times*, no surgeon finds a place on the committee. Surely, also, the scientific side of the question should be represented, and a member of the medical profession who has devoted himself mainly to laboratory work should also have been selected. Finally, the experience of general practitioners, who have been obliged to treat patients in their own homes, would have been of the utmost value. For these reasons, Sir, among others, I venture to utter a protest against the composition of the committee, feeling sure that the members of the profession generally would look with more favour on the work of the committee had the members thereof been selected with a more open mind. As the committee is constituted at present it is almost comparable to the Christian Scientists forming a committee of their own number to pronounce upon the value of their cult.

In the *Times* of Feb. 20th appeared an excellent and suggestive letter from Dr. E. J. Steegmann pleading for a continuance of the research on tuberculosis commenced by the Royal Commission. It is sincerely to be hoped that his contentions will be acted upon, but unless the constitution of the Chancellor's committee be modified there is reason to fear the free and liberal spirit required will be wanting.

I am, Sir, yours faithfully,

Feb. 26th, 1912. F.R.C.P.

THE MEDICAL PROFESSION AND THE NATIONAL INSURANCE ACT.

To the Editor of THE LANCET.

SIR,—On p. 537 of your current number Dr. W. J. Le Grand, after quoting the words of the first paragraph of Part II. of the Fourth Schedule of the above-mentioned Act—viz., "(1) Medical treatment and attendance for any persons dependent upon the labour of a member"—asks some questions thereon.

The word "dependent," *as used in this Act*, is defined in Section 79, and may comprise very much more than the "wives and children" of insured persons, particularly if the far-reaching definition given in Section 13 of the Workmen's Compensation Act be resorted to. This statement probably will answer Dr. Le Grand's first question as it now stands; but if we shift the word "only" (in the question) so as to make it the seventh instead of the fourth word, the question will read thus: "Does it apply to relatives of *only* members of approved societies?"—an entirely different question, but the one which, I think, Dr. Le Grand really means to ask. It will be found that, with one exception, "additional benefits" are confined, and intentionally so, to those who are "members" of approved "societies." This is made clear by the very wording—not only of the first paragraph itself "..... members" ["members" of what?], but also by that of the many sections in the Act in which "additional benefits" are mentioned.

An approved society may give "additional benefits" to insured persons who are "members" of that "society" if there happens to be a sufficient surplus following a Treasury valuation of the assets and liabilities of the society, which valuation may be made at irregular times and after irregular intervals, although, presumably, every three years—Sections 36 and 37. Observe "society" and "member."

The proviso to Section 9 (1) confers a favour which, although not specifically an "additional benefit," is practically such, but the favour is confined to "members" of approved societies. Section 9 (2) deals with cases (of reduction of

rate of benefit) as to which a society *or* the Insurance Committee administers the benefit, and the society *or* Insurance Committee has to make provision for the grant of *additional* benefits, whatever these may be, which are mentioned in the long list of such which is given in Part II. of the Fourth Schedule; and for these the society *or* the Insurance Committee will have to pay. This is the exception in which it is stated clearly that the Insurance Committee has to administer some "*additional* benefits." All other sections contemplate the *society* paying for any of the additional benefits in the list.

All this seems to point to the idea that the original, central, and controlling method of working the entire Act was by and through the societies, and the societies alone. Section 13 deals with those only who are "members" of an approved society. Section 14 (1) "..... additional benefits shall be administered by the society or branch of which the persons entitled thereto are *members*, *except* where such benefits are *in the nature of medical benefits*, in which case they shall be administered by, and through, the Insurance Committees."

Now, notwithstanding that the 14 paragraphs in Part II. of the Fourth Schedule are headed "Additional Benefits," it yet may become a question whether paragraph 1 can be said rightly to deal with a "medical benefit" at all, although it mentions something "in the nature of a medical benefit." The paragraph says "medical treatment and attendance," and not "medical benefit," as we find in Section 8 (1) (a) and Section 15 (1). To the extent that paragraph 1 may be said to deal with "additional benefit," the societies would administer for their "*members*"; to the extent that it is concerned with what is "in the nature of medical benefit," the societies are excluded and the Insurance Committees alone take up the work—i.e., *pay*. There is no definition in the Act of the phrase "medical treatment and attendance."

Elements of doubt might creep into Section 15 (2), Section 15 (4), and Section 17 (1). Thus, Section 15 (1) the Insurance Committee, for the purpose of medical benefit, makes arrangements with practitioners, &c.; (2) says that the arrangements shall secure that insured persons shall be attended by practitioners with whom arrangements are made, but it does not exclude the possibility that the arrangements may secure something additional, such as subsidiary arrangements for "medical treatment and attendance" on those who may happen *not* to be insured—e.g., "dependents" of those who *are* insured. Again, Section 15 (4), which mentions "*persons*" (not "insured persons" nor "members") entitled to receive "medical attendance and treatment," might be said to include "dependents." And finally, Section 17 (1), which deals with *sanatorium* benefit being extended to dependents of insured persons, says that in such a case the Insurance Committee shall arrange "for the treatment of such dependents." It does not say "for the sanatorium treatment" or "for such treatment," and he would be a bold man who would fly in the face of the plain meaning of words as they have been been arranged and declare that, "of course, *sanatorium* treatment is meant." If sanatorium treatment was meant it ought to have been stated, and since the marginal note is no part of an Act of Parliament, the marginal note here cannot be prayed in aid. A document must be interpreted as it is worded, and not as something else which the framer may have intended but did not express.

Whatever body, whether Insurance Committee *or* society, arranges the "rate of remuneration" for the work mentioned in paragraph 1 of Part II. of the Fourth Schedule with the practitioners (if any such will be forthcoming for the purpose) will have to pay.

I am, Sir, yours faithfully,

Lincoln's Inn, Feb. 26th, 1912. BERNARD O'CONNOR.

To the Editor of THE LANCET.

SIR,—We, the undersigned, being medical officers of Medical Missions in Great Britain and Ireland, beg to declare that we believe that the "National Insurance Act" will affect medical missions adversely in the following ways:—

1. Patients will not be allowed to choose mission doctors unless such doctors are on an approved panel, and there appears to be but little chance that these salaried officers will find a place on such a panel.

2. Subscriptions must necessarily decrease as the usual subscribers to medical missions will find it difficult or impossible to pay their share of the insurance contribution and subscribe to a charity.

3. The personal relationship between doctor and patient, which is a prominent factor in medical missions and a helpful part in the progress of the case, will to a great extent be lost when the patient is treated under contract practice.

We are, Sir, yours faithfully,

SIDNEY BOYD, M.S., F.R.C.S.

THE CHOLERA EPIDEMIC.

(FROM THE BRITISH DELEGATE TO THE CONSTANTINOPLE BOARD OF HEALTH.)

A SOMEWHAT prolonged absence from Constantinople has prevented me from continuing the record of the cholera epidemic in this and adjoining countries from the point to which it was brought in my last letter on the subject.[1] The excellent summary of the epidemic, however, which appeared in the Annus Medicus on Dec. 30th, 1911, has to a great extent filled the gap, and it only remains to add the following few additional details to supplement that summary and bring the record down to the present date.

Cholera in Russia.

The 1911 epidemic of cholera in Russia was an exceptionally mild one. It came to an end on Oct. 30th (Nov. 12th). The total number of cases for the whole Russian Empire was put at 3313, and that of deaths at 1596. These figures are in striking contrast with the 216,091 cases and 101,002 deaths recorded in the 1910 epidemic. They may reasonably justify the hope that the cholera infection has now lost most of its virulence in Russia, and that there may perhaps be no revival of the disease there in the coming summer. The epidemic of last year was almost entirely confined to the valley of the Volga and some of the Caucasian provinces.

Cholera in Constantinople.

The epidemic here rapidly declined (after the date of my last letter), as shown by the following figures:—

Week ending Sept.	4th	.....	324	cases,	155	deaths.
,,	,,	11th	.....	258	,,	145	,,
,,	,,	18th	.....	256	,,	140	,,
,,	,,	25th	.....	131	,,	91	,,
,,	Oct.	2nd	.....	181	,,	97	,,
,,	,,	9th	.....	179	,,	119	,,
,,	,,	16th	.....	52	,,	48	,,
,,	,,	23rd	.....	15	,,	6	,,
,,	,,	30th	.....	5	,,	1	,,

The totals since the beginning of the epidemic, on May 21st, were 2619 cases and 1484 deaths. The outbreak was rather more severe and more prolonged than that of 1910. The above figures do not include cases and deaths occurring among the troops in the capital. Such cases continued to occur in the garrison until the end of the year and well on into January. As recently as Jan. 14th one case, and on the 17th two cases were seen among the Constantinople troops, in spite of the cold weather prevailing at the time. A revival of the disease in the spring in this city must be regarded as almost certain.

Cholera Elsewhere in Turkey.

It will be impossible to give in detail, even if space permitted, the history of the epidemic in the Turkish provinces.

[1] THE LANCET, Sept. 16th, 1911, p. 853.

The returns received have been incomplete and irregular. The following figures have been officially published. It will be seen that the bulletins were issued at very unequal intervals, but the figures have a relative value sufficient to justify their publication. Before August 21st the bulletins gave no totals for the whole country. From that date onwards the totals were as follows :—

Bulletin of August		21st	... ...	163	cases,	152	deaths.
,,	,,	22nd	... ...	107	,,	124	,,
,,	,,	22nd (bis)	...	178	,,	151	,,
,,	,,	23rd	... ...	262	,,	228	,,
,,	,,	28th	... ...	86	,,	89	,,
,,	,,	30th	... ...	162	,,	115	,,
,,	,,	30th (bis)	...	155	,,	139	,,
,,	Sept.	4th	... ...	188	,,	228	,,
,,	,,	6th	... ...	164	,,	222	,,
,,	,,	6th (bis)	...	402	,,	607	,,
,,	,,	11th	... ...	352	,,	335	,,
,,	,,	11th (bis)	...	550	,,	560	,,
,,	,,	16th	... ...	207	,,	210	,,
,,	,,	16th (bis)	...	277	,,	285	,,
,,	,,	19th	... ...	303	,,	348	,,
,,	,,	19th (bis)	...	293	,,	270	,,
,,	,,	23rd	... ...	358	,,	338	,,

The above figures referred to no clearly defined periods of time Where two bulletins were issued on the same day they contained fresh figures (usually for different parts of the country), and the figures did not overlap. After Sept. 23rd an attempt was made, but not very successfully, to publish records at more or less fixed intervals, as shown in the following bulletins :—

Date of bulletin.	Period covered.	Cases.	Deaths.
Sept. 30th	Sept. 15th to 23rd ...	557 ...	682
Oct. 8th	Sept. 23rd to Oct. 1st ...	489 ...	555
,, 18th	Oct. 2nd ,, ,, 10th ...	426 ...	604
,, 27th	,, 11th ,, ,, 19th ...	519 ...	527
Dec. 10th	,, 19th ,, Dec 1st ...	1006 ...	1078
" 15th	Dec. 1st ,, ,, 8th ...	32 ...	29
,, 26th	,, 8th ,, ,, 18th ...	41 ...	933
Jan. 6th, 1912	,, 18th ,, ,, 30th ...	34 ...	34
,, 10th, ,, ...	,, 30th ,, Jan. 6th ...	37 ...	49
,, 24th, ,, ...	Jan. 6th ,, ,, 21st ...	53 ...	50

The rise in deaths in the bulletin for Dec. 8th to 18th was due to a severe outbreak of cholera among pilgrims at Mecca, 651 out of the 933 deaths figuring in that bulletin being ascribed to that city. But this figure was itself below the truth. From information received from the Board of Health's officials in the Hedjaz towns it may be gathered that the following has been the course of the cholera epidemic in that province in recent months.

The first cases in Mecca were seen on Sept. 1st, when three Javanese pilgrims from Singapore were found to be ill with the disease. The epidemic rapidly gained ground, and by Oct. 1st 366 cases and 329 deaths had been recorded. For the next seven weeks there were few or no fresh cases ; but on Nov. 21st, when the fêtes of Kurban Bairam were drawing near and the number of pilgrims at Mecca was approaching its maximum, cholera reappeared. In a week over 200 fresh cases had occurred, and by Dec. 20th the totals (including the September returns) amounted to 1648 cases and 1565 deaths.

In Medina the disease was first seen on Sept. 7th, when the bodies of two pilgrims from Malibar were found dead, and death was shown to have been due to cholera. These men had come from Mecca, so that apparently Medina obtained the infection from that city and not from the north, although a few cases of cholera were occurring in Damascus at about that time. The disease did not spread very rapidly (the numbers of pilgrims in Medina would be small at that period) ; by Nov. 19th 190 cases and 157 deaths had been recorded. No cases occurred subsequently, and Medina seems to have escaped reinfection by the pilgrims returning from Mecca after the fêtes. No cases occurred also at the Tebuk lazaret on the Hedjaz railway, and it is noteworthy that on this occasion cholera does not appear to have spread northwards by land from Mecca, though many cases (about 30) occurred among pilgrims arriving at The Tor lazaret by sea from Jeddah and Yanbo. At Jeddah 323 cases and 310 deaths were recorded between Dec. 2nd and 25th.

At Damascus 1 case of cholera occurred in August (in a pilgrim from Angora) ; in September the disease became epidemic there ; and between Sept. 8th and Nov. 5th 143 cases and 115 deaths had been registered.

Mesopotamia and Irak-Arabi (the regions round the north end of the Persian Gulf) were also visited by the disease. In the Bagdad vilayet 492 cases and 345 deaths were recorded between May 29th and Oct. 28th. (In the previous winter 819 cases and 723 deaths were registered in this vilayet between Oct. 16th, 1910, and Jan. 2nd, 1911.) In the Basra vilayet, after a few cases in July, cholera reappeared on Oct. 20th, and between that date and Oct. 27th 366 cases and 260 deaths occurred there. In the Bahrein Islands some 200 or 300 deaths from cholera were recorded in the months of November and December.

The latest bulletin for the whole of the Turkish Empire, bringing the returns down to Jan. 21st, shows that cholera was then still present at Janina, Loros, Biredjik, Aintab, Adana, Tarsus, Angora, Panderma, Hodeidah, Acre, and Kharput (or in the neighbourhood of these places)—that is to say, the infection was still present in such widely separated regions as Albania, Asia Minor, Syria, Palestine, and the Yemen. Later telegrams from Aleppo also show that cholera exists there.

Cholera in other European Countries.

For the present cholera is quiescent in European countries other than Turkey. The three last bulletins from Italy state that in the week ending Dec. 24th 35 cases and 14 deaths were recorded, in that ending Dec. 31st 6 cases and 1 death, and in that ending Jan. 7th no cases or deaths. All these cases and deaths had occurred in the Caltanisetta, Girgenti, and Syracuse provinces of Sicily, and none on the mainland.

An official statement was recently issued by the Austrian Government to the effect that during the year 1911 88 cases of cholera and 40 deaths were registered in the whole of Austria. These were distributed as follows : 6 cases and 3 deaths in Lower Austria (including Vienna) ; 2 cases and 1 death in Styria ; 70 cases and 32 deaths on the coast (including 42 cases and 16 deaths in Trieste) ; and 10 cases with 4 deaths in Dalmatia (at Cattaro and Arlu). The totals for Hungary are not given ; the disease was still present there in December ; between Dec. 10th and 16th 19 cases and 12 deaths were seen in four different places in Hungary, and between Dec. 17th and 23rd 2 cases and 1 death.

Constantinople, Feb. 14th, 1912.

MOTORING NOTES.

(FROM A SPECIAL CORRESPONDENT.)

Concerning Various Auxiliary Methods of Suspension.

Although the ordinary laminated spring fulfilled its purpose as regarded the horse-drawn vehicle, the advent of the modern motor-car and the high speeds consequent on its use have called for a further device to take up the vibrations occasioned by the rapid motion, especially on bad roads. These vibrations, the result of road inequalities, are due to the consequent rebound. Many attempts have been made to overcome these drawbacks, which cause discomfort to car passengers and slipping of the tyres on the road with its excessive wear of the tyres. Elastic spring shackles, such as are fitted on the Daimler, Rover, and Standard cars, are a favourite means. The "Hobson," made by Messrs. Hobson, Limited, of Vauxhall Bridge-road, is of this type, and so is the "Amortisseur J. M.," sold by Messrs. Jacquet, Maurel, and Condac, of 92, Gloucester-road, London. These can be fitted without modification to the existing framework of almost any make of car. The last-named shackles are enclosed in a cylindrical casing, which protects against the entrance of dirt and helps also to resist any tendency towards side-play. The "Telesco," made by the Polyrhoe Carburetters Company, of 144, Great Portland-street, combines, in addition, a sort of liquid dash-pot, a method employed on many kinds of machinery, in which work is absorbed to neutralise the rebound.

Practically it is the rebound that causes the greater part of the discomfort. An ideal solid dash-pot method has been introduced in the Gabriel Rebound Snubber, sold by Messrs. Brown, Brothers, Limited, of Great Eastern-street, London, E.C. This consists of a half-circle base secured to the frame

of the car by a clamp with a set screw; the other half of the circular base is suspended on a stud and sleeve, around which is a coil spring. The base is encircled by four coils of Balata belting, faced with a flexible metal band and enclosed in a dust-proof case. The belting is fastened to the axle by an adjustable clamp. When the car strikes an obstruction the springs compress, the expansion of the coil spring takes up the slack in the Balata belting, and as the spring starts to rebound, the coils of metal-faced belting passing over each other create a friction that increases as the coil spring compresses, thus steadying the car-springs and really making the car "forget to jar." I tried the snubber on a road after having driven over the same route on a car not fitted with it, and noticed a great difference; bumps previously felt were conspicuous by their absence, and the deadening effect to rebounds was most marked.

The Atlas Triple Expansion Pulsating Tyre Pump.

The old saying that "the luxuries of one age are the necessities of the next" certainly applies to motoring accessories. A few years ago most motorists had to pump up their tyres by hand, and but few indulged in labour-saving mechanical contrivances. Now the hand inflation of tyres is being replaced by less laborious devices. A turn at the pump may be invigorating as exercise, but it is inconvenient when engaged on a professional round. Motoring doctors, therefore, will welcome the pulsating pump, recently introduced by the Atlas Non-puncture Inner Case Syndicate, Limited, of High-street, Kensington. All that is needed is to remove a sparking plug and to turn the pump into the exposed tapping by hand. The union nut is attached to the top of the pump, and the screw hose coupling to the tyre stem; the engine is started and the air-gauge shows when the desired pressure has been obtained. There is no need to stop the engine when changing to another tyre. The pump can be attached to any car in less than three minutes, and will inflate a tyre in less than four. The only point to remember is to run the engine slowly, for the pump will not operate at its full efficiency if the engine is permitted to race.

Concerning Carbonisation.

The deposit of carbon on the piston of a petrol engine is one of the commonest causes of pre-ignition and "knocking," and occurs sooner or later with all internal combustion motors. The length of the period of immunity depends greatly, if not absolutely, on the care of the owner in regulating the quantity of lubricating oil that his motor receives, though its quality is also a factor. Curettings from pistons and cylinder walls have shown, in addition to carbon deposit, a certain amount of road grit, which might be obviated by an efficient filter over the air intake. Carbon removers have been introduced, but it is as well to adjust the flow of lubricating fluid to the minimum needed by the engine prior to experimenting with them. If efficacious, they are simpler than dismantling the engine to scrape the piston. Still, the use of a good brand of lubricant (such as the products of the Vacuum Oil Company, Messrs. Duckham and Co., Messrs. Wakefield, and Messrs. Butterworth), and *not more than is needed of it*, is preferable. An up-to-date means of rendering unnecessary the removal of the cylinder covers is the oxygen jet ignition, which consists of opening all the available orifices and directing a jet of flame and oxygen gas on all the carbonised surfaces. This method, which is known as Watkin's patent, can be carried out at the premises of Messrs. Sully and Co., Limited, 10, Old Town Clapham, S.W. I understand that other depôts for this treatment will shortly be available.

A Useful Motor Glove.

The Continental Tyre and Rubber Company, Limited, who are probably known to all motorists as makers of excellent tyres, also produce a comfortable motor glove, with a palm of leather and a back of a special waterproof material. These gloves are comfortable and keep the hands perfectly dry.

The Daimler Sliding Sleeve Engines.

Those interested in this type of engine should write to the Daimler Company for a copy of a little booklet recently issued entitled, "Some Points Concerning the Daimler Sliding Sleeve Engines." This explains in detail the working of these engines and their advantages, and includes drawings to show the operation of the sleeves.

The De Dion Bouton Motor Carriages for 1912.

THE 1912 catalogue of Messrs. De Dion Bouton, Limited, which has just been issued, is above the average level of such publications. In addition to illustrations of the numerous types of their carriages it contains interesting descriptions of the structure of their cars, which can be read with advantage by the owners of any make of car.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Health of Liverpool.

THE medical officer of health's latest report to the health committee showed a considerable fall in the annual rate of mortality. The rate was 19·9 per 1000 of the inhabitants, as compared with a rate of 22·6 per 1000 a year ago; or a decrease of 37 in the total number (288) of deaths registered during the week. It was inevitably among the aged and the young that the mortality predominated; 58 persons who had reached the age of 70 years, and 81 not exceeding a year old being cut off. The principal causes were respiratory and tuberculous diseases, chiefly the former. In the corporation hospitals last week there were 632 patients, the largest number and the most serious cases being those of phthisis.

A Wireless Telegraphy Station at the University of Liverpool.

Unmistakable evidence of the progressive character of the University is furnished by the fact that a wireless telegraphy station has been installed in connexion with the electrical engineering department. It is an experimental station, intended to enable students to obtain some practice in the operation of the system. An aerial conductor, 150 feet high, with a horizontal length of about 600 feet, has now been erected between the central tower above the electrical engineering laboratories on the west side of Brownlow-street and the Victoria Tower of the University in Brownlow-hill. The apparatus has been designed by Professor Marchant and constructed by his staff of students. It has received the official recognition of the Postmaster-General.

West Derby Guardians and the Certification of Pauper Lunatics.

At the recent meeting of the West Derby board of guardians approval was given to a recommendation of the finance committee that in the event of a medical practitioner being called in at Mill Road Infirmary to certify cases of detention under the Lunacy Act only the services of medical men residing in the union shall be obtained. This resolution partakes of the nature of a "pious opinion" on the part of the guardians, as it really rests with the magistrate, on duty for the occasion, to "call to his assistance" any qualified medical man whom he may desire, even though he may not have "paid rates in the union."

Banquet to Sir William and Lady Lever.

It has been arranged by the staff of the Liverpool School of Tropical Medicine to entertain Sir William and Lady Lever at dinner on their return from South Africa. The dinner will take place at the Adelphi Hotel this week. The Earl of Derby (Lord Mayor of Liverpool and honorary Vice-President of the school) has kindly consented to preside. Sir William Lever is the chairman of the School of Tropical Medicine.

The Fellowship of the Royal Society and the University of Liverpool.

Liverpool is much gratified at the selection by the Royal Society of two of its professors, Professor Benjamin Moore and Professor Robert Newstead. The former is the Johnston professor of bio-chemistry at the University of Liverpool. He is distinguished for his researches in physiological chemistry, especially in the domain relating to the equilibrium and metabolism of cells. Professor Moore has made important advances by his application of physico-chemical methods to the solution of biological problems. He is one of the joint editors of the *Bio-Chemical Journal*. Professor Newstead

occupies the Dutton memorial chair of entomology at the University and has done important work in connexion with the School of Tropical Medicine.

Feb. 27th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Sex of School Medical Inspectors.

THE Lancashire Education Committee at its recent meeting decided to advertise for a school medical inspector. A discussion took place as to whether female inspectors should be debarred from applying. It was pointed out that a medical inspector for the county authority was somewhat different from that of a medical inspector of a county borough. The county inspector had a great deal of hard travelling to do and many extra difficulties to contend with. It was decided to confine the appointment to male applicants.

Day Nurseries.

An institution such as the Salford Day Nursery for Children, which has carried on its work for 22 years, and which is open each day except Sundays, for taking care of babies who cannot walk at a charge of 4*d.* daily, and for older children at 2*d.* a day, is worthy of support from the public. The attendance averaged about 20 a day, a total of 4998 during the year. The children's pence amounted to £54 and the subscriptions and donations to £74.—At the nineteenth annual meeting of the Manchester Day Nursery, which is situated in the crowded centre of Hulme, it was stated that last year there were 2912 attendances and during the past 14 years a total of 38,382. The Poor-law contribution to the funds is, with the approval of the Local Government Board, to be quadrupled. At this institution the charge for children is 3*d.* a day. One speaker at the meeting eulogised "the application of life-saving methods such as this," pointing out at the same time that there is a direct relation between the rate of infant mortality in a great city and the number of mothers who had to go out working with no one to take proper care of their children in their absence. Another speaker pointed out that the Home for Lost Dogs had received more support during the year than the Hulme Day Nursery. There were about 3000 attendances yearly, and each child received three meals, the cost of each of which was barely ½*d.*

Henshaw's Blind Asylum: its Work and its Financial Needs.

At the annual meeting of the subscribers to Henshaw's Blind Asylum it was stated that there was again a heavy deficiency on the year's working. The asylum gives the very best education, both elementary and technical, to 200 boys and girls and adults in the schools, and in addition the asylum authorities place within the reach of their pupils the means of livelihood which the blind people themselves above all things desire. In their own workshops they have 60 blind men and women, most of whom lived in houses of their own. They also gave weekly grants, amounting in the aggregate to £1000 a year, to aged and infirm blind people who were unable to work. About one-half of the blind people in the country lost their sight after reaching adult age, often after they had settled down in homes of their own with wives and children. The asylum educated, trained, and employed close upon 400 blind people ranging from infancy to old age. The annual expenditure was £2984, with a deficiency on the income and expenditure account of £978, and an actual deficiency on the year of £1169. Hence the necessity for an appeal for more funds if the usefulness of the institution is to be maintained.

Feb. 27th.

NEWCASTLE-ON-TYNE.

(FROM OUR OWN CORRESPONDENT.)

The College of Medicine.

THE annual meeting of the council of the University of Durham College of Medicine was held recently, Professor Sir G. H. Philipson, President of the College, being in the chair. Others present were Professor P. Bedson, Professor R. Howden, Professor T. W. McDowall, Mr. Cecil Cochrane, Mr. Alderman Cromie, Mr. J. E. Gibson, Mr. W. J. Sanderson, and Dr. J. T. Merz. The annual report of the council was approved for submission to the annual court of governors. Referring to the year's work, the report stated that the work had been carried on in compliance with the regulations of the Board of Education, and it was expected that a substantial grant on the year's work would shortly be paid by the Board. Further, it was stated that an agreement had been arrived at between the honorary staff of the Royal Victoria Infirmary and the council of the College, by which it was hoped that the clinical instruction in the infirmary would be recognised for the purposes of a grant by the Board of Education. The result of an appeal for funds to pay off the debt on the new buildings and to provide endowment had been disappointing. Several changes in the staff were notified. Dr. T. Eustace Hill, medical officer of health of the county of Durham, succeeds Dr. H. E. Armstrong in the chair of public health. Dr. F. A. Bainbridge is now professor of physiology, vice Sir Thomas Oliver, who has resigned this chair and has been appointed adjunct in the chair of medicine, already held jointly by Sir G. H. Philipson and Dr. David Drummond. Professor Bainbridge's appointment is the first instance of a whole-time professor of physiology in Newcastle.

Royal Victoria Infirmary.

The annual court of the governors of the Royal Victoria Infirmary was held on Feb. 24th. There was a large attendance under the presidency of the Lord Mayor, Sir William Stephenson. The reports from various committees were received and adopted. The Lord Mayor, in moving the adoption of the general report, alluded to the illness of Sir Riley Lord and to the death of Lady Oliver. It was agreed to send letters of condolence to Sir Riley Lord and to Sir Thomas Oliver. Sir William Stephenson further pointed out that for the first time the current income had met the current expenditure, and that the deficit of £3000 of last year had been turned into a surplus of £856. The most satisfactory feature about the income was that the amount of money subscribed by the workmen continued to increase year by year. Reference in one of the reports occurred to a new admission scheme, which provides that instead of admissions coming through various members of the honorary staff, all admissions shall be made through one portal and one medical authority. This would so regulate the system of admissions that each patient would get a fair turn, having strict regard to the question of urgency. In future, it was intended to make strict inquiry into the social condition of the patients, so that those who could afford to pay for outside medical aid should not be allowed to abuse the benefits of the hospital and keep out deserving cases. The cost of the new scheme would be about £4500, and it would be complete in about six or eight months. In the analysis of the subscriptions committee, Mr. Charles Irwin observed that the Northumberland miners during the past year had contributed £4232, and the Durham miners £4619. From the county of Durham, however, they had had 425 more cases than from Northumberland, and for these additional cases Durham had only paid £387. During the last six years there was a deficiency of £7125 in the receipts for the cases received from Durham. In reply to a question, Mr. Irwin stated that the miners of Northumberland paid £4 14*s.* 5*d.* per patient and the miners of Durham £3 9*s.* 10*d.* per patient. The remarks made in connexion with the new admission scheme and those above in connexion with the finance of the infirmary may be taken together and afford material for thought. It is certainly to be hoped that the new admission scheme may be able to grapple with the question of hospital abuse. Whether it will be more than a pious hope is doubtful when the remarks above quoted from the subscriptions committee are considered. The opening speech of the chairman, the statement of the finance committee that the workmen's contributions had gone up £1541 during the past year, and also that only another £1000 were needed to make these contributions into the round sum of £20,000, and the calculation of the amount subscribed per patient by different sections of the community as shown by Mr. Irwin, seem to point to the desirability of the system of coöperation by means of small weekly contributions, such as are given by the workmen of this district. The principle of contributions is proper, but there is the tendency locally to regard such contributions as "something paid to a club," and consequently necessitating a return. That

this is no mere vague idea is clear from the nature of the question asked concerning relative contributions by the Northumberland and Durham miners. Whether in these circumstances the new admission scheme will be able to work is doubtful. It may, perhaps, be remembered that I found it necessary to make observations similar to these on the occasion of the presentation of other annual reports, and the same tendency which prompted those remarks last year is to be seen in the proceedings of this year's annual court of governors at the infirmary.

Feb. 26th.

BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

The University of Bristol and Agricultural Research.

A SHORT time ago allusion was made in these columns to the offer made by the Board of Agriculture to the University of Bristol of a capital sum of £5000 and an annual grant of £3500, subject to certain conditions. These were the absorption of the existing Fruit and Cider Institute into the station which the Board wishes established; the local contribution of a capital sum of £5000; and the application of £300 a year, left by the late Lord Winterstoke for agricultural research, to the upkeep of the station. Lady Greville Smyth has subscribed £1000, and sums of £500 each have been promised by Lord Portman and the Right Hon. Henry Hobhouse, while other subscriptions and promises bring the total up to £3500. The balance of £1500 should be readily forthcoming in a district where the general prosperity is so closely bound up with that of agriculture.

Queen Victoria Jubilee Convalescent Home, Bristol.

At the recent annual meeting, presided over by the Lord Mayor of Bristol, Mr. F. W. Wills, the report showed that 1971 patients had been received during the year; there had been no deaths, and the great majority of patients had been much benefited. The total expenditure had been £2794 0*s.* 7*d.*, about £30 less than in the preceding year. The income for the year was £3206 6*s.* 10*d.*, consisting mainly of revenue from investments and income-tax rebate. Mr. Herbert M. Baker, chairman of the Bristol General Hospital committee, spoke of the indebtedness of this and kindred institutions to the home, which had received 680 patients from the hospital, 673 from the Royal Infirmary, 30 from the Eye Hospital, 72 from the Bristol Dispensary, and 17 from the Clifton Dispensary. He referred to the possible effects of the Insurance Act on voluntary institutions, and said that he believed the alarm felt in some quarters was largely unnecessary. The value of the home, he said, might be further gauged by the fact that the average daily number of inmates was 80, the cost per head being about £35 per annum.

An Unqualified Practitioner at the Bristol Coroner's Court.

Fortunato Vigna, describing himself as "M.D., U.S.A.," and alleging that he had a Turin degree in medicine, gave evidence at a Bristol inquest on a woman who died from malignant disease, but who had been treated by him for indigestion, constipation, and rheumatism; he also stated in his evidence that he had suspected "kidney trouble." The friends of the deceased had been induced to call in "Dr." Vigna by a newspaper advertisement of the "Cosmopolitan Homœopathic Institute for the Cure of Chronic Diseases," which, it was said, had a large and experienced staff of graduated and fully qualified assistants. Cross-examination proved that this staff consisted of Vigna and one or two other unqualified persons. It appeared that Vigna had three or four such establishments in Bristol. The jury added a rider to their verdict to the effect that frauds of this type should be suppressed.

The Bristol Medical Mission.

The annual meeting of the friends of the Bristol Medical Mission was held on Feb. 23rd. The medical report stated that 8176 patients had been treated at the dispensary, and 2087 cases had been visited at their homes. The financial statement showed an unfavourable balance of £44.

The Remuneration of Workhouse Medical Officers.

At the meeting of the Bristol board of guardians held on Feb. 23rd it was stated that three lady medical practitioners had applied for the post of assistant medical officer at Eastville workhouse. The salary is £125 per annum, with rooms and rations. After some discussion Miss H. I. Moss was elected. The Rev. A. Bray, who opposed the appointment, according to the local press, stated "that it was a cheese-paring policy which was responsible for the fearful state of chaos they had in the two workhouses. They were only appointing the lady because they could not get a man; and they could not get a man because they were not paying sufficient money."

A District Medical Officer's Salary.

At the last meeting of the Newton Abbot (Devon) board of guardians the medical officer for the Kingsteignton district applied for an increase in salary. He stated that his salary was 11*s.* 6*d.* weekly, which would hardly pay for the cost of the medicines. He added that there were very few vaccinations to be performed, and the "association nurse" attended most of the midwifery cases. Last year she attended 39 out of the 53 confinements. After some discussion the matter was referred to a committee.

The British Dental Association.

The Western branch of the British Dental Association held its winter meeting on Feb. 17th at the Devon and Exeter Dental Hospital. There was a good attendance, under the presidency of Mr. J. J. H. Sanders, of Barnstaple. Mr. Frederick Sleep (Plymouth) read an amusing paper on the Dental Aspect of Idiosyncrasy, Susceptibility, and Responsibility. Mr. R Willcox (Clifton) contributed an interesting paper on Pyorrhœa. Dr. Brennan Dyball, the anæsthetist to the Devon and Exeter Hospital, gave an interesting demonstration on the Combination of Ethyl Chloride and Ether for Dental Operations.

Enteric Fever and Shell-fish.

The medical officer of health of Devon, Mr. G. Adkins, in his report states that during the past quarter 31 cases of enteric fever were notified, and of these 3 were due to eating raw cockles.

Royal West of England Sanatorium, Weston-super-Mare.

The annual meeting of the subscribers of the Royal West of England Sanatorium was held on Feb. 17th. The medical report stated that during 1911 the patients admitted numbered 2045 (1037 men, 1008 women). This number was 277 less than in 1910, and the reduction was due to the facts that the sea-water baths were unavailable for six weeks, and that some patients stayed longer than usual. 1496 patients remained in the institution for 14 days, while the remaining 549 remained for longer periods up to three months. The financial statement showed that the income amounted to £4482, and that the sanatorium was free from debt.

Isolation Hospitals for Devonshire.

At the meeting of the Holsworthy (Devon) rural district council, held on Feb. 21st, the medical officer of health, Mr. W. G. Gray, reported that a scheme had been proposed by which Devon would be divided into four or five sanitary districts, each provided with an isolation hospital, and probably a medical officer of health would be appointed for the districts. Mr. Gray added that the Local Government Board inspector, Dr. R. J. Reece, had commented strongly on the need of isolation hospitals in the county, for between Plymouth and Devonport and Barnstaple there is practically no isolation hospital, and no isolation accommodation exists at Tavistock, South Molton, Okehampton, Broadwoodwidger, or in the Bideford rural district.

The West Cornwall Infirmary, Penzance.

Sir Clifford Cory, M.P., has sent a cheque for £400, being his first year's salary as a Member of Parliament, to the West Cornwall Infirmary. The gift will be very acceptable, as an adverse balance of about £300 exists against the charity, and funds were required for refurnishing and decorating the institution.

The Victoria Hospital, Swindon.

At the annual meeting of the subscribers of the Victoria Hospital, Swindon, it was stated that £1000 had been

bequeathed by Miss Bell, of South Marston. The King Edward Memorial Fund brought to the institution an endowment of £1080.

Feb. 27th.

WALES.

(FROM OUR OWN CORRESPONDENT.)

The Welsh National Memorial.

THE executive committee of the Welsh National Memorial has appointed as chief medical director Dr. Marcus S. Paterson, at present medical superintendent of the Brompton Hospital sanatorium at Frimley. One of his first duties will be to prepare a scheme for the provision of sanatoriums for the whole of Wales and Monmouthshire. Progress is being made towards the acquisition by the committee of the West Wales Sanatorium at Allt-y-Mynydd, about six miles from Lampeter, in Carmarthenshire. This institution, which has accommodation for 20 patients, has been in active working since July, 1908, the annual expenditure averaging £1500. It is situated on the slope of a hill, 850 feet above sea level, in grounds 13½ acres in extent. It is constructed of stone obtained in the neighbourhood, and is well designed for its purpose. The initial cost, exclusive of the land, was about £400 per bed. The land is held on lease for 999 years at an annual rental of £11 4*s*. It is proposed, if the institution is taken over by the memorial committee, that the sum of £10,000 shall be credited to the memorial fund from the three counties of Carmarthen, Cardigan, and Pembroke. The conditions on which the sanatorium committee suggests that the sanatorium should be transferred are that the management, together with all obligations as regards staff and buildings, should be taken over by the memorial committee from July 1st next, and that until adequate provision for sanatorium benefits for the whole of Wales and Monmouthshire is provided priority of admission should be reserved for patients coming from the three counties named. It is further suggested that life governors of the sanatorium should be asked to forego their claims to recommend patients for treatment in the institution. The Cardiff board of guardians is taking definite steps to provide for those under its charge a sanatorium in the neighbourhood of Penarth, and at some distance from the Cardiff workhouse. The question of special sanatorium provision is being considered by boards of guardians in other parts of Wales, but in view of the contemplated action of the memorial committee, that body has asked the various boards to delay taking action in the direction indicated.

Aberdare Isolation Hospital.

Although the town of Aberdare has an industrial population of over 50,000 persons it is very ill-provided with accommodation for isolating cases of infectious disease. At the time of a small-pox scare in 1873 a corrugated iron building was erected, but until the appointment of Dr. Morgan Rees as medical officer of health some eight years ago it was hardly ever used, although cases of infectious disease which ought to have been removed were rarely absent from the town. Dr. Rees made good use of the hospital during his term of office, and demonstrated that the inhabitants were quite willing to take advantage even of the meagre accommodation it afforded. He also proved the need for a larger institution, and one more in accordance with modern ideas. Pressure from their own medical officer of health, added to the insistent demands of the Glamorgan county council, at last induced the members of the urban district council to take steps to provide a more suitable hospital, and a few years ago plans were chosen after competition among architects, and a site was decided upon. The consent of the Local Government Board was not at first obtained for the loan it was intended to procure, but after falling in with some of the suggestions of the Board a second attempt is now being made, and a formal inquiry has been made on behalf of the Board by Dr. S. W. Wheaton. The proposed site is the property of the council, and it is expected that the buildings will cost about £20,000, a sum equal to £400 per bed. The plans show accommodation for three diseases. For scarlet fever patients there are to be 20 beds, including four in a convalescent block; for diphtheria, 18 beds, also including four for convalescents; and for typhoid patients 8 beds are provided. In addition to these there is provision for four patients in an observation block.

Feb. 27th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Carnegie Trust for the Universities of Scotland.

THE annual meeting of the Carnegie Trust for the Universities of Scotland was held in London on Feb. 22nd. Lord Elgin presided, and in presenting the report referred in the first place to the fact that the work of the past year completed the first decade in the history of the Trust. During the ten years £1,000,000 had passed their hands. The grants to the universities were fixed for quinquennial periods after visitation by a committee of the trustees, when every care was taken to discover the most urgent claims in each university. He could bear testimony to the improvements in the equipment of the universities which were visible at each visitation. With regard to the increased grants promised by the Treasury, it was possible that the trust operations might be affected thereby, but probably more as to the direction in which assistance might be given than in alteration of the amount. The alteration in the regulations as to payment of class fees which had become necessary last year owing to the insufficiency of revenue to meet the claims had been carried out without any difficulty or friction. Beneficiaries of former years had been continued on the old system. The adoption of the report was seconded by Lord Reay, and Sir Donald MacAlister and Sir James Donaldson spoke in appreciation of the work of the scheme. The report of the executive committee for the year 1910–11 shows the total income for the past ten years to have been £1,062,931. Of this, £63,546 were expended on research, £368,288 in grants to universities and colleges, £445,373 in payment of class fees for students numbering 11,480, and £30,158 in administration. Referring to the endowment of research, the report shows that in the past year there had been no falling off in either the quantity or quality of the output of work. In the departments of biology and medicine the report of the examiner states that the standard of excellence exhibited by the beneficiaries had been higher than it had ever been since the trust came into existence. Applications for fellowships, scholarships, and grants for the year 1911–12 must be lodged on or before April 1st with the secretary of the trust. The laboratory of the Royal College of Physicians had proved an important supplement to the research scheme. The laboratory was purchased in 1903 under an agreement for five years with the Royal College of Physicians and the Royal College of Surgeons under which these bodies agreed to continue their respective annual contributions of £750 and £200 towards working expenses. This agreement was renewed in 1908 for a further period of five years. Exclusive of the capital sum of £10,000 invested in the purchase of the buildings, the total sum expended on the laboratory had been £14,011 2*s*. 3*d*., and the excess of expenditure over income which had been met by the trust under the agreement amounted to £5215 12*s*. 9*d*.

Memorial to Lord Lister.

The Lord Provost of Glasgow presided on Tuesday over a meeting to consider the subject of a memorial to the late Lord Lister. There was a large attendance, many prominent medical men being present, and it was unanimously agreed that a memorial should be erected in Glasgow, where the Listerian doctrines first took practical shape. A committee was appointed to consider the suggestions as to the form which the memorial should take, and this committee will make a private report before a public meeting is held.

Feb. 27th.

TUBERCULOSIS AND SANATORIUM TREATMENT.—A lecture on this subject will be given at the Central Hall, Renshaw-street, Liverpool, on Tuesday, March 5th, at 8 P.M., by Mr. C. H. Garland, chairman of the Benenden Sanatorium, Kent. The Earl of Derby has consented to preside, and all interested in the subject are invited. Communications may be addressed to the medical officer of health at the municipal offices, Liverpool.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Dublin Hospitals and the Insurance Act.

FOR some months past a committee, representative of the several Dublin hospitals, has been considering the probable effects of the National Insurance Act on the interests of the hospitals. In a letter published last week in the daily papers this committee invites the moral and material support of the public, declares that the subscriptions must fall off, but that the demand for service is not likely to diminish, and concludes as follows: "This crisis threatens the utility and existence of institutions the sole function of which is to alleviate stricken and agonised humanity by unremitting, unresting, and unquestioning solicitude. To prevent such a calamity we most anxiously urge the benevolent public not to relax their interest or reduce their subscriptions or gifts unless and until they are satisfied that the usefulness and needs of the hospitals have abated."

The Royal Hospital for Incurables.

The governors of the Royal Hospital for Incurables have decided to abandon the scheme of providing additional accommodation for advanced cases of tuberculosis. In view of the opposition roused among the residents in the neighbourhood, the managing committee thought it right to consult the general body of the governors, with the result stated. It is unfortunate that the beneficent scheme of the managing committee has been defeated by an opposition based largely on misunderstanding.

Death of Two Distinguished Irish Medical Men.

The deaths have occurred during the week of two distinguished Irish medical men—Dr. Henry FitzGibbon, consulting surgeon to the Royal City of Dublin Hospital, and Sir Francis R. Cruise, consulting physician to the Mater Misericordiæ Hospital.

The Tuberculosis Committee.

The constitution of the Tuberculosis Committee gives rise to some criticism from the Irish point of view. Only two members of a committee of nearly 20 are from Ireland, and these are both public officials. It is perhaps desirable that the Local Government Board and the Insurance Commissioners should be represented, but there should also be some one who could face the problem from the point of view of the practising physician.

High Death-rate in Irish Towns.

The death-rate in the various Irish towns during the month of February has been abnormally high. In the week ending Feb. 10th the rate in the Dublin registration area was 26·6 per 1000 per annum, and in Belfast it reached the enormous figure of 41·7, though it has now dropped very considerably, the last recorded rate being 26·9.

Honours for Irish Medical Men.

Two medical men have been appointed High Sheriffs for 1912—viz., Mr. J. J. O'Sullivan for the city of Waterford, and Mr. Charles McDonnell for the city of Limerick. Surgeon-General W. J. Fawcett, A.M.S. (retired), of Leecarrow, Carrick-on-Shannon, has been appointed a Deputy-Lieutenant of the county of Leitrim.

The Samaritan Hospital, Belfast.

At the annual meeting of the supporters of the Belfast Samaritan Hospital held on Feb. 20th it was reported that during the past year 529 extern and 279 intern patients had been treated. Ninety major operations were performed. There is a debt of £340 on the hospital, and strong recommendations were made by the speakers as to the importance of increased financial support for this most excellent and useful institution.

The Ulster Hospital for Women.

In aid of the new buildings of the Ulster Hospital for Women Lady Jaffé held an exhibition and sale of dolls at her house on Feb. 26th, which was a very great success, and which will considerably add to the finances of that institution.

Feb. 27th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Microsporon Disease of the Scalp in School Children.

WITHIN the last few years there have been several outbreaks of microsporon disease in Vienna public schools. Under our compulsory system of education these schools are attended by children belonging to all classes of the population, and the authorities recognising the danger of an extension of the infection invited Professor Riehl to lecture, before an audience of officers of public health, on the disease in question. The present series of outbreaks commenced in Vienna in the year 1909, and since that time over 1000 cases have been noted. Professor Riehl said that the disease was caused by the fungus called microsporon, and that a considerable epidemic of a precisely similar nature had also occurred in Paris. The general health of the affected children was in no danger, but the loss of hair in various places over the head was most unsightly. As it was important to recognise the existence of this condition as early as possible it would be necessary to examine each child in this respect. The clinical appearance of the affected head was very significant, the whitish-grey scabs and the short stumps of the broken hairs being conspicuous objects. The treatment by means of X rays and the application of a disinfectant hair lotion was simple and effective, and the necesary exposures to the X rays could be easily given in the special departments of the hospitals in Vienna. Professor Riehl advised regular inspection and notification of each case as absolutely essential for the suppression of the disease. He thought that isolation of the patients was not required, as in his opinion a dressing well applied over the head was sufficient to prevent dissemination of the infection.

The New Deaf and Dumb Institution.

In a few days the inmates of the old institution for deaf and dumb children will move into their new home, a short distance from Vienna. It will accommodate 150 boys and 50 girls, and satisfies all the requirements of modern hygiene. The old institution, which is now to be pulled down, has had a long and interesting history. In 1779, when the school was founded, it had only 12 pupils (6 boys and 6 girls), but at a later period 120 children could be received as inmates, and they were kept there until they were completely able to make themselves understood, and to earn their living. The institution afterwards served chiefly as a training school for teachers of the deaf and dumb, whilst the patients were admitted only from Vienna itself, the other towns and counties erecting separate schools for the deaf and dumb children of their own populations. Finally, the old institution accommodated only 40 boys and 20 girls. The teachers were early trained in the oral teaching of the inmates according to the so-called German method, whilst the "French" method of conversing by means of the fingers was abandoned as soon as the other system had become known. Important medical investigations into the etiology of congenital deafness and deaf-mutism were conducted in this home.

Growth of the Embryonic Heart after Separation from the Body.

In a paper read before the Gesellschaft der Aerzte, Professor Braus, of Heidelberg, who was present by invitation of this society, described experiments which he had made with the hearts of certain animals in the embryonic stage. After giving a historical sketch of the previous endeavours to make the heart live and grow after separation from the body, he said that he had been able to do so by keeping the organ in a liquid equivalent to physiological solution of chloride of sodium. He found that amphibia gave the best results. He could keep and examine the heart of the embryo of the frog in a mixture of fresh plasma from a frog with the tissue-juice of the frog. It was a very delicate operation to remove the heart from an embryo having a length of not more than one-fifth or one-sixth of an inch. In his experiments he succeeded in observing the rhythmic contractions of the organ and its growth for periods varying from three to ten days. The heart subjected to this kind of "cultivation" had no muscles or nerves, but the transmission of irritation took place by means of the plasmoderma, the fine fibres connecting the cells in the embryonic organ.

Feb. 26th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Insanity in New South Wales.

THE annual report of the Inspector-General (Dr. Eric Sinclair) sets out that the total number of insane under observation in New South Wales on Dec. 31st, 1910, was 6177, an increase of 243, a rate much above the yearly average. The proportion of insane to general population was 1–274, which is the same as the last few years. There is still an excess of patients over the available accommodation. A new asylum to be built at Orange has not yet been begun, and that opened at Norwich has merely relieved overcrowding and not removed it. The provision of temporary accommodation has seemed a lesser evil than prolonging the overcrowding, and this has had to be entered upon. Two old buildings were adapted for temporary occupation, and at some other places calico dormitories were added. The report states that the present Lunacy Act requires amending, and particularly to provide for the admission of voluntary patients to hospitals for the insane and licensed houses. The ward for uncertified cases at Darlinghurst has been more largely made use of. The staff here is an honorary and visiting one. The reception houses at Darlinghurst and Newcastle have done good work, and slight and curable cases avoid the penalty of certification in removal to asylum. The amount expended in maintenance during 1910 was £181,482, an increase of £14,000. The average cost per patient was £31 15*s.* 9½*d.* A sum of £31,000 was collected by the Master in Lunacy towards maintenance, thus lessening the actual cost to the State.

Prevention of Venereal Disease.

After much negotiation it has been announced that the Victorian Government has arranged with the authorities of the Alfred and Women's Hospitals to set apart a ward for the treatment of venereal diseases. No charge of any sort will be made, and patients will be encouraged in every way to submit themselves to treatment for a requisite period. This step has been taken on the advice of a committee of medical men appointed some time ago to assist the Government in outlining measures for the prophylaxis of venereal disease.

Education Congress.

A congress is to be held in Melbourne in March for the purpose of endeavouring to organise educational work in Victoria, so that a continuous course may be open from the primary schools to the university. Various public bodies have been asked, and have consented, to coöperate, and the Victoria branch of the British Medical Association has nominated Dr. J. F. Wilkinson (President) and Dr. A. V. Anderson and Dr. R. H. Fetherston as representatives. One of the principal speakers will be Professor R. J. A. Berry, of the Melbourne University, and Dr. J. W. Barrett, C.M.G., is the chief organising spirit. The congress will continue over four days, and a social programme will be carried out.

Suicide by Lysol.

The city coroner for Melbourne recently remarked that he had investigated the deaths of 30 persons during the last 12 months who had committed suicide by taking lysol. The fashion in suicide appears to change, for a few years ago "Rough on Rats" was the favourite destroying agent, and more recently infusions of wax-match heads had a vogue.

New Year Honour.

Among the knighthoods conferred at the New Year was that given to Dr. C. K. Mackellar, of Sydney. Sir Charles Mackellar is one of the best-known public men in Sydney, and has always taken a prominent part in movements for promoting the public health. Some years ago he was President of the Board of Public Health, and has more recently interested himself in the care of neglected children. Apart from professional interests, he has been a Member of the Legislative Council for many years, and is concerned in many large financial enterprises, being chairman of directors of the Bank of New South Wales. He has left for a trip to England, accompanied by his daughter, who recently published a volume of verse entitled "The Closed Door."

Infantile Diarrhœa.

An unfortunate situation recently arose at the Children's Hospital, Perth, owing to a lack of water-supply and the impossibility of obtaining fresh milk. A number of patients were suffering from diarrhœa, and according to the statement of the resident medical officer, "children were dying like flies." Aroused by the seriousness of affairs, the Government sent up six milch cows from the State farm, and the situation was temporarily overcome. The Government is considering the establishment of a herd of 200 cows and a milk-supply modelled on that of the Lady Talbot Institute of Melbourne.

Sickness and Accident.

The Registrar of Friendly Societies in New South Wales has stated that "experience has shown that the mining members of the friendly societies carry a 38 per cent. higher risk than other members, yet all pay the same contribution." In connexion with this statement a deputation recently waited upon the Registrar and asked for advice upon the matter. Mr. Trivett pointed out that the question was really one of accident assurance. The situation would be met either by the enforcement of higher contributions from miners or by a reduction of sick benefits or by treating accident as a separate benefit.

Miner's Phthisis.

The report of a Royal Commission appointed by the West Australian Government has been presented to Parliament. Its chief recommendations include the certification of all miners before employment as being sound within three months of first engagement. Within three months of the passing of an Act every existing miner must submit to medical examination. If found free from tubercle he is to have a certificate to that effect. If found infected, no employer under a penalty may continue to employ him. Periodical examinations of all men shall be made at six-monthly intervals and those found tuberculous shall be so notified (1) to themselves, (2) to their mine managers, and (3) to the Board of Health.

Memorial Window.

A handsome window in stained glass has been placed in St. Thomas's Church, Moonee Ponds (a suburb of Melbourne), to the memory of the late Dr. J. W. Y. Fishbourne, who died about three months ago. The memorial is the work of the parishioners of the church and the people of the district in which the late Dr. Fishbourne resided for many years.

Export of Pork.

The Victorian Government has extended the provisions of the Milk and Dairies Supervision Act to the whole State. This has been done in order to encourage an export trade in pork, and to ensure the absence of tuberculosis from all pigs, which was found to be common in districts not previously under the Act.

Jan. 20th.

Obituary.

ALFRED HARRY YOUNG, M.B., C.M. EDIN., F.R.C.S. ENG., LL.D. ST. AND.,

EMERITUS PROFESSOR OF ANATOMY IN THE VICTORIA UNIVERSITY OF MANCHESTER, ETC.

WE regret to announce the death, at the age of 60, of Professor A. H. Young, formerly professor of anatomy in the Owens College and the Victoria University of Manchester, which occurred at his home in Didsbury on Feb. 22nd.

Professor Young was born in Warrington, and his intention, after receiving a good education, was to study dentistry. With this object he began his studies at University College, Liverpool, but under the advice of the late William Mitchell Banks, then professor of anatomy at Liverpool, he decided to go to the University of Edinburgh and qualify for a medical career. He took the degrees of M.B. and C.M. in 1876, and, his leaning at this time being towards surgery, proceeded to the English F.R.C.S. diploma in 1880. After a short period spent as a junior demonstrator of anatomy under Sir William Turner in Edinburgh, Young went to Manchester, where he became demonstrator of anatomy in 1877–78, under Professor Morrison Watson. He

also acted as a demonstrator in physiology under Professor Arthur Gamgee. He held in succession the posts of pathological registrar and medical and surgical registrar at the Royal Infirmary. Shortly before this time a hospital for consumption was founded in Manchester, and Young, in 1882, was elected an honorary surgeon to this institution. In 1883 he became surgeon to the Salford Royal Hospital, a post which he held for many years along with the professorship of anatomy. At that time pathology was being taught with great efficiency by the late Professor Dreschfeld, but as Dreschfeld was a busy practitioner, he could not give more than a certain amount of time to the duties of the chair. The important section of pathology known as "surgical pathology" was entrusted to Young, who did the work remarkably well. But the tragic death of Professor Morrison Watson left the chair of Anatomy vacant in 1885, and to it Young was elected. He also acted as dean of the medical school for a long period of years, and exerted a considerable influence both directly and indirectly on its fortunes. He was always solicitous for the progress of the medical school and for the comfort of its students, who were keenly attached to him. He was an active, precise, and painstaking teacher. His powers as a draughtsman, so invaluable to the anatomical demonstrator, he utilised with the greatest skill. He was also an innovator as a lecturer, for he taught certain subjects from the embryological point of view long before this method was extensively adopted in this country.

Young had a vigorous and strenuous personality, kind and sympathetic, but never disguising his well-matured opinions, which he always expressed with perfect candour and fairness. He was a steadfast and devoted friend and unwearied in carrying out any policy which he felt constrained to adopt. During his professorship the anatomical department was well served by the assistants whom he selected, Professor Robinson of Edinburgh, Professor Peter Thompson of Birmingham, and Professor Paterson of Liverpool, among others holding demonstratorships under him. Three volumes of "Studies Issued from the Anatomical Department" (Vol. I. in 1891, Vol. II. in 1900, and Vol. III. in 1906) contained Young's work on the morphology and abnormalities of blood-vessels and the placenta. He wrote, also, the chapters on general embryology and the vascular system in Cunningham's "Text-book of Anatomy."

Professor Young was a recognised authority on education, was selected as an examiner in his subjects by many universities, and when representing the University of Manchester on the General Medical Council took an active part on the Education Committee.

The funeral took place at the Manchester Crematorium on Feb. 26th, and was attended by many former colleagues on the Senate and Council of the University as well as many friends and former pupils. Professor Young leaves a widow and one daughter.

MAXWELL OGILVY-RAMSAY, M.D. EDIN., F.R.C.S. EDIN.,

HONORARY SURGEON TO THE CUMBERLAND INFIRMARY.

THE death of Dr. Maxwell Ogilvy-Ramsay took place on Feb. 15th at his residence, Portland-square, Carlisle, after only a few days' illness. He caught a chill while performing his professional duties, and pneumonia developing he passed away, to the deep grief of a wide circle of friends and patients.

Dr. Ogilvy-Ramsay was born in 1864 at Kirriemuir and was the third son of the Rev. Dr. Ogilvy-Ramsay, the parish minister of Kirriemuir. He received his medical education at the University of Edinburgh, where he graduated M.B., C.M. in 1890. After acting as house surgeon at the Royal Infirmary, Edinburgh, he subsequently held a similar position at the Hospital for Sick Children in Liverpool, and later went to the Rotunda Hospital in Dublin, where he obtained valuable experience in midwifery, one of the subjects to which he was specially attached. In 1892 he took the Licentiateship of the Royal College of Surgeons of Edinburgh, and in the following year was elected a Fellow of the College. He then started general practice in Carlisle, and his wide professional knowledge and skill as an operator soon won for him an assured position.

Shortly after he had settled at Carlisle attention was directed by the Government to the need for some reform in the obstetric work of the city, and a committee of ladies was formed with the object of organising a scheme for the provision of a trained midwife. A nurse was appointed to the post and Dr. Ogilvy-Ramsay consented to give his assistance in difficult cases, which assistance he continued in an honorary capacity until the passing of the Midwives Act. In 1895 he proceeded to the M.D. degree of the University of Edinburgh, taking for his thesis the subject of the prevention of sepsis in midwifery. In this year he also obtained the M.A. degree, and by an interesting coincidence his father received the degree of D.D. on the same occasion. In 1903 he was appointed honorary assistant surgeon to the Cumberland Infirmary, and in the following year joint surgeon with Dr. H. A. Lediard.

Dr. Ogilvy-Ramsay in his younger days was an athlete of no mean order, and during his professional career took part in most of the popular forms of recreation, including, of course, the "roaring game" of curling, in which he excelled. Somewhat reserved in his manner to strangers, he had a warm heart, and his sympathy and kindness, integrity and unselfishness inspired in his friends an esteem which bound them to him. By patients of all classes he was greatly loved. In 1893 he married Miss Andrews, of Lichfield, who survives her husband with two children, a daughter and a son. The interment took place at Closeburn on Feb. 17th.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced: Dr. Dittmar Finkler, who had very recently resigned the chair of hygiene in the University of Bonn. In early professional life he had been assistant to Professor Pflüger and *privat-docent* of physiology. He then took to clinical work and was assistant to Professor Rühle, and afterwards had charge of the University Policlinic. The Ministry of Education selected him as General Commissioner to represent the German Universities at the Chicago Exhibition, and after his return he was charged with the establishment of a Hygiene Institute, and appointed to the chair of that subject. He was a man of very varied accomplishments, and published papers on Physiology, Pathology, Clinical Medicine, Food Problems, and Bacteriology. His death occurred during his sixtieth year.—Dr. Reye, who was for many years director of the State Asylum at Friedrichsberg. He was 80 years of age.—Dr. William Alfred Grünhagen, formerly extraordinary professor of physiology and of medical physics in the University of Königsberg. He edited Wagner and Funk's well known text-book on physiology, and published as long ago as 1873 a monograph on electro-motor behaviour of living tissues. He was 69 years of age and had lived in retirement for the last 18 years.—Dr. Sigismund Rahmer, well known in literary circles. His writings include studies of Heine, Strindberg, Lenau, and especially Heinrich von Kleisch. He was 45 years of age and a general practitioner in Berlin.—Dr. Emil Stoffella, Ritter d'alta Rupe, extraordinary professor of medicine in the University of Vienna, aged 76.—Dr. Waldemar Koch, professor of physiological chemistry, a nephew of Professor Robert Koch.—Dr. Etienne Cestan, professor of clinical surgery in the University of Toulouse.—Dr. Ch. Guende, professor of clinical ophthalmology in the Marseilles Medical School.

H.R.H. Prince Arthur of Connaught has consented to become Patron of the Twenty-seventh Congress of the Royal Sanitary Institute be to held at York in July next.

LORD LISTER AND UNIVERSITY COLLEGE, LONDON.—The committee and professorial board of University College have sent a letter to Mr. J. J. Lister, F.R.S., expressing sympathy and regret at the death of Lord Lister. The letter recalls with pride that Lord Lister received his medical education within the walls of the College and of University College Hospital, and records high appreciation of the supreme value of his labours in the field of biological and medical science, as a result of which he was enabled to introduce improvements and methods which have reformed surgical practice and have been of incalculable benefit to humanity by prolonging life and alleviating suffering. The letter is signed by Lord Reay and Dr. T. Gregory Foster.

THE NATIONAL INSURANCE ACT.

BRITISH MEDICAL ASSOCIATION: SPECIAL REPRESENTATIVE MEETING.

THE Special Representative Meeting was intended to conclude on Wednesday night, Feb. 21st, but, as we stated in the report in our last issue, it was necessary to continue the meeting on Thursday, Feb. 22nd. The first part of the morning was spent in debating a motion of want of confidence in the Council, and many members took part in the discussion. The solicitor to the Association, at the request of the Chairman, answered various questions with regard to the position of the Association in the event of a wholesale resignation of the Council following the passing of such a motion. It appeared that under the Articles and By-laws a temporary state of deadlock might arise. After both sides had expressed their views with some energy, a motion that the Committee proceed to the next business was carried by a large majority. A motion advising each division to hold a general meeting as soon as possible after the Representative Meeting was agreed to, and it was also decided that a manifesto stating the objections of the profession to the Act should be prepared for presentation to the press, Members of Parliament, deans of medical schools, university tutors, and headmasters of public schools.

The meeting expressed its high appreciation of the action taken by the Royal Colleges of Physicians and Surgeons in defence of public and medical interests; and recorded its strong condemnation of the expressions used by Mr. Lloyd George with reference to the Colleges. A proposition that the Council be instructed to promote united action with the medical corporations and other representatives of professional interests in order to secure conditions satisfactory to the profession was referred to the Council. The motion that the rest of the report be approved was passed by a substantial majority and the committee stage then ended.

Dr. E. J. MACLEAN, on resuming the chair, proposed a vote of thanks to Mr. T. J. Verrall for his great ability in presiding over the Committee stage. Dr. T. A. HELME, in seconding, paid a high tribute to Mr. Verrall's fairness, and the motion was carried with enthusiasm. The meeting then considered in order the resolutions passed during the Committee stage, and, with certain modifications, these were all agreed to. The meeting closed with a vote of thanks to the Chairman, proposed by Mr. N. BISHOP HARMAN and seconded by Dr. HELME. In answer to a question during the morning, it was announced that the signatories to the Association pledge numbered in July, 1911, 18,000; in November, 1911, 23,000; and in February, 1912, 26,100.

NATIONAL MEDICAL UNION.

We have received the following communication from the National Medical Union:—

Sections of the Union have already been formed or are in the process of formation in the following centres: Ashton-under-Lyne, Hyde, Birkenhead, Colwyn Bay, Eccles, Huddersfield, Liverpool (Southern), Liscard, Oswestry, Ross (Herefordshire), Rochester and Chatham, Rochdale, Wigan, Winchester, Wrexham, and Bolton, and conveners of meetings for the formation of other sections have already been appointed. Very good progress has already been made, and it is hoped that many districts which are still undecided will follow the lead of several of the great centres and complete the establishment of local sections of the National Medical Union. Necessity for the formation of these sections has become more urgent since the recent action of the Representative Meeting of the British Medical Association in proposing a conference with the Insurance Commissioners before the six cardinal points were adequately guaranteed. All communications concerning these sections may be directed to the honorary secretary of the Organisation Subcommittee, Dr. M. Russen Rhodes, Bridge House, Didsbury, Manchester.

Medical News.

UNIVERSITY OF BRISTOL.—At examinations held recently the following candidates were successful:—

FINAL EXAMINATION FOR THE DEGREES OF M.B., CH.B.

Pass.—Edwin Vincent Foss, John Richard Kay-Mouat, and Percy Moxey.

Part I.—George Frederick Fawn and William Peach Taylor.

FINAL EXAMINATION FOR THE DEGREE OF B.D.S.

George Frederick Fawn.

EXAMINATION FOR THE DIPLOMA IN PUBLIC HEALTH.

Thomas John Williams.

FOREIGN UNIVERSITY INTELLIGENCE.—*Basle:* Dr. Max Iselin, who has charge of the surgical side of the University policlinic, has been recognised as *privat-docent* of surgery.—*Berlin:* Dr. Krückmann, professor in Königsberg, has been appointed Professor of Ophthalmology in succession to Dr. von Michel; and Dr. Cramer, professor in Göttingen, has been appointed to the Chair of Mental Diseases in succession to Dr. Ziehen retired. Dr. L. Rabinowitsch Kempner has been granted the title of Professor. This lady took the degree of Ph.D. in Berne in 1894 and since then has worked in Berlin under Professor Koch and Professor Orth.—*Berlin (Military Medical Academy):* Dr. Kurt Roscher, senior staff surgeon, has been appointed head of the Sanitary Department in place of Professor Rudolf Salzwedel.—*Breslau:* Dr. C. Prausnitz, director of the Rabies Institute, has been recognised as *privat-docent* of Hygiene.—*Budapest:* Dr. Karl Engel has been recognised as *privat-docent* of Diseases of the Circulation and Digestion.—*Erlangen:* Dr. Ernst Engelhorn has been recognised as *privat-docent* of Midwifery and Gynæcology.—*Freiburg:* Dr. Otto Kahler, of Vienna, has been offered the chair of Laryngology in succession to Dr. Killian.—*Göttingen:* Dr. Max Voit, of the Anatomical Institute, has been promoted to be Extraordinary Professor.—*Heidelberg:* Dr. Karl Wilmanns, assistant physician in the Clinic for Mental Diseases, has been granted the title of Extraordinary Professor. Dr. Czerny has been appointed Honorary President of the International Committee for Cancer Research.—*Jena:* Dr. L. Wrede, *privat-docent* of surgery, has been promoted to be Extraordinary Professor.—*Kiel:* Dr. Walter Birk has been recognised as *privat-docent* of Children's Diseases.—*Leipsic:* Dr. E. Heller has been recognised as *privat-docent* of Surgery.—*Lemberg:* Dr. Kasimir Knietniewski, extraordinary professor of comparative anatomy, has been promoted to be Ordinary Professor.—*Prague (Bohemian University):* Dr. Christian Hynek has been recognised as *privat-docent* of Medicine.—*Würzburg:* Dr. Karl Hess, who has just declined an invitation to the chair of ophthalmology in Berlin to succeed von Michel, has been decorated with the Order of the Bavarian Crown, which carries with it a title of nobility.—*Zürich:* Dr. Wilhelm Schulthess, *privat-docent* of orthopædic surgery, has been promoted to be Extraordinary Professor.

BRITISH MEDICAL BENEVOLENT FUND.—The annual general meeting of subscribers to the British Medical Benevolent Fund was held on Feb. 20th, when the present officers were re-elected and a committee appointed for the ensuing year. Dr. S. West, the treasurer, presented his financial statement for 1911 and announced that subscriptions amounting to £1980 8*s.* 6*d.* and donations amounting to £347 14*s.* 6*d.* had been received for the grant department, whilst help had been given to 216 applicants, the sum so disbursed being £2362 16*s.* 6*d.* The annuity department had received an income of £3048 7*s.* 2*d.* derived from investments in trust securities, and the sum of £2593 15*s.* had been paid to the pensioners, of whom there are 131 on the books. Legacies received during the year had amounted to £2380, including £1000 from the executors of the late Dr. F. W. Pavy, a Vice-President of the Fund, and £1000 left by Mrs. John Lowe in memory of her husband, who was for many years chairman of the committee of the Fund. After the report of the committee had been received the meeting was adjourned until 4.30 P.M. on Wednesday, March 13th, when the Lord Mayor has kindly consented to preside at a gathering at the Mansion House in support of the Fund. The adoption of the report will then be moved by Bishop

Boyd Carpenter, the other speakers being Sir Thomas Barlow, President of the Royal College of Physicians of London, Mr. Rickman J. Godlee, President of the Royal College of Surgeons of England, Sir T. Clifford Allbutt, Regius Professor of Physic at Cambridge, Sir John Tweedy, and Dr. West.

A SOMERSET CENTENARIAN.—Mr. W. Edwards, of West Monkton, died recently at the age of 100 years.

DONATIONS AND BEQUESTS.—Under the will of the late Mrs. Ellen Penn, the Miller Hospital, Greenwich, will receive £3000, and the St. John's Hospital, Lewisham, £2000.

MIDDLESEX HOSPITAL.—After the great success achieved last year by the production of *The Belle of New York* by amateurs in aid of the Middlesex Hospital, the experiment is to be tried again this year. A company of over 70 ladies and gentlemen are rehearsing a new and original musical play, entitled *The Military Girl*, written and composed by Charles and Muriel Scott-Gatty. The performances will be at 8.30 P.M., from April 16th to 20th, at the Savoy Theatre, kindly lent for the occasion by Mrs. D'Oyly Carte. Notices as to where tickets are obtainable will be issued later.

DEVON AND EXETER HOSPITAL.—The annual meeting of the subscribers to this hospital was recently held. The medical report stated that during 1911 the in-patients were 1647, against 1614 in 1910. The out-patients numbered 5116, as compared with 5014 in the previous year. The average daily number of in-patients was 160, and the average stay in hospital 35 days. The financial statement showed that the ordinary income was £9972 and the ordinary expenditure £11,512. Legacies were received during the year amounting to £1341, and £1000 were given by Mrs. G. Walker for the endowment of two cots.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

National Insurance Commission.

THERE has been laid on the table of the House of Commons a copy of a memorandum on the steps taken preliminary to the operation of Part I. of the National Insurance Act.

International Opium Convention.

The text of the International Opium Convention signed at the Hague on Jan. 23rd, 1912, has been communicated to Parliament in an official White Paper.

Dogs' Protection Bill.

Sir FREDERICK BANBURY has presented a Bill in the House of Commons for the purpose of prohibiting experiments on dogs. The measure is "backed" by Mr. GEORGE GREENWOOD and Mr. FIELD, and has been read a first time.

Small-pox and Infantile Mortality Statistics.

A return has been ordered by the House of Commons, on the motion of Mr. RAMSAY MACDONALD, which will provide in the first place statistics showing for each year from 1890 to 1910 the number of deaths from small-pox in England and Wales. These figures will be given in considerable detail. In the second place, the return will set out for each year from 1890 to 1910 inclusive the deaths of infants under one year of age per million births from each of the following causes: syphilis, scrofula, tuberculous peritonitis, and tabes mesenterica; skin diseases, erysipelas, pyæmia, and phlegmon; bronchitis, diarrhœa, atrophy, and debility (including premature birth).

The Increase of the Feeble-minded.

Amongst the notices of motion for Tuesday, Feb. 27th, in the House of Commons was one in the name of Mr. HOUSTON, which related to the increase of the feeble-minded. The terms of the honourable Member's motion were as follows: "That in view of the great and rapid increase of feeble-minded, unhealthy, and useless members of the community, a Commission should be appointed to consider the advisability of adopting such drastic methods as sterilisation to arrest the increase of undesirable subjects in the United Kingdom." As the motion was the fourth on the notice paper no opportunity was found for moving it.

Abolition of Vivisection Bill.

Mr. LANSBURY has introduced in the House of Commons a bill "to provide for the abolition of vivisection." The members who support him in doing so are Mr. KEIR HARDIE, Sir JOHN ROLLESTON, Mr. CHANCELLOR, Mr. WILLIAM THORNE, Mr. JOHN WILSON, Mr. TYSON WILSON, Mr. JOHN TAYLOR, Mr. JAMES THOMAS, Colonel LOCKWOOD, Mr. SNOWDEN, and Mr. ALBERT SMITH.

Asylum Officers (Employment, Pensions, and Superannuation) Bill.

Lord WOLMER has presented a Bill in the House of Commons "to limit the hours of employment of officers and servants in asylums and to amend the Asylum Officers' Superannuation Act, 1909." It has been read a first time. The honourable Members backing the Bill are Mr. CHARLES ROBERTS, Mr. STANIER, Mr. WATSON RUTHERFORD, Mr. HIGHAM, Mr. MCCALLUM, Mr. WARDLE, Mr. COTTON, Mr. CHARLES CRAIG, Mr. WILLIAM REDMOND, Sir DAVID BRYNMOR JONES, and Sir REGINALD POLE-CAREW. The framers of the Bill have had before them the report of the Select Committee of the House of Commons, which considered last year the various matters with which the measure deals.

The Capital of India.

In the debate in the House of Lords last week on changes in Indian policy some comment was made on the sanitary condition of the proposed site of the new capital at Delhi. Lord CURZON OF KEDLESTON pointed out that it had been subject to inundations. The Marquis of LANSDOWNE alluded to the successful efforts which had been made to improve the sanitary condition of Calcutta, to its broad avenues and abundant water-supply. One thing, he said, was established, and that was that the sanitary condition of Delhi was inferior to that of Calcutta. He also referred to an ailment called "the Delhi boil," which he understood was to be found at the new capital of India. An American investigator had been devoting a considerable amount of attention to this mysterious complaint, which lasted about ten months.

HOUSE OF COMMONS.

WEDNESDAY, FEB. 21ST.

Qualified Medical Practitioners in India.

Mr. H. W. FORSTER asked the Under Secretary of State for India how many duly qualified medical practitioners there were in India, how many of these were men, how many were women, and how many of either sex were in the service of the Government of India.—Mr. MONTAGU wrote in reply: As no system of medical registration exists in India it is impossible to give an exact answer to the first part of the question, although approximate figures could probably be obtained from non-official publications. As regards the Government service, lengthy and somewhat complicated consultation of the official lists for the various provinces, and probably even reference to the Government of India, would be necessary to arrive at the statistics asked for. I shall be glad to have the matter investigated for the honourable Member and let him know the result as soon as it is obtained.

National Insurance Act Topics.

Sir RANDOLF BAKER asked the Secretary to the Treasury whether it was proposed that approved societies should pay salaries to their secretaries, sick visitors, or inspectors out of funds raised under the operation of the Insurance Act from their members, whether societies would be allowed to institute a medical test for new members, and, if so, whether the fees for medical examination might be paid out of the administration expenses fund.—Mr. MASTERMAN answered: Approved societies are authorised by the Act under Section 3 to pay such salaries, if any, as may be required to secure visitors and inspectors subject to the limitation of general administration expenses to be fixed by regulations of the Commissioners. The institution of a medical test is optional to the societies, and, if enforced, must be borne either by the individual concerned or out of the amount to be set aside for the administration expense fund of the society.

Answering a series of questions Mr. MASTERMAN said: The Insurance Commissioners recognised from the first their duty to supply authentic information and advice to persons affected by the Insurance Act, especially in view of the most important decisions which over 14 millions of insured persons must necessarily take before next July unless they sink into the class of deposit contributors. In the absence of any permanent staff, who in established Government departments provide information, both by lectures and otherwise, concerning all new Acts of Parliament to persons affected, all four Insurance Commissions engaged persons for temporary assistance for this purpose. The engagements were, of course, entirely non-political. It may interest the honourable gentlemen to know that they included two ex-Unionist candidates for Parliament, and that one of the two English organisers, who also arranged the general course of instruction, is the late secretary of the Unionist Insurance Committee. The English Commissioners, at meetings held at the Foreign Office with representatives of Friendly Societies and trade unions, were strongly urged in the first instance to limit themselves to private conference with members of the various organisations concerned. A large number of very successful conferences have been held, and through such conferences they hope that the necessary information may be conveyed to the bulk of insured persons; but they recognise that in the case of women and the remoter rural districts some further methods will have to be devised. In Scotland, Ireland, and parts of Wales, where the ground is not covered by Friendly Societies, it has been found impossible to convey the required information through such organisations, and lectures and addresses are therefore being given open to all who are interested in the Insurance Act. All the conferences and lectures are non-political and uncontroversial in character. The lecturers are under instructions to make no political allusion, direct or indirect, to be careful not to dogmatise on any doubtful points of law, and to confine themselves to plain exposition of what is now the law of the land. Never at any time has there been any connexion between the Government insurance organisation and the body now called the Liberal Insurance Committee, nor did any of the lecturers of the Commission attend the meeting of the Liberal lecturers addressed by the Chancellor of the Exchequer on Feb. 1st.

Leaflets explanatory of the Act are in preparation and will shortly be issued. The enormous number of letters of inquiry received—quite beyond the possibility of treatment by the present staff of the Commissioners—has demonstrated at once the necessity for this work and also the amazing misunderstanding which prevails concerning the details of the Act by which the interests of many persons affected by the Act would be seriously prejudiced. A Paper is in preparation detailing the work already done by the Commissioners to bring the Act into operation, which will include a full account of this preliminary work of exposition. I propose to add to the Paper a list of the permanent and temporary appointments (other than clerical) at present made by the National Insurance Commissioners and the Joint Committee and to lay it on the table of the House.

THURSDAY, FEB. 22ND.

The Italian Government and Red Crescent Expeditions.

Mr. DILLON asked the Secretary of State for Foreign Affairs whether he could state on what grounds the Italian Government withdrew the permission given by them last autumn to a Red Crescent expedition to proceed by sea from Egypt to Tripoli; whether it was at present possible for supplies or *personnel* connected with Red Crescent societies to go from Egypt to Tripoli; and, if not, whether the British Government would request the Italian Government to withdraw their prohibition.—Sir E. GREY replied: I have been informed that the objections of the Italian Government to the despatch of the Red Crescent Mission by sea were based on a report from General Caneva contending that the landing of such a mission at the time would be regarded by the local population as a reaffirmation of Turkish influence in Tripoli. The Italian Government further argued that, as other missions organised by the Red Crescent had entered Tripoli from Tunis, the Turkish orces were already amply provided in this respect. They also entertained apprehensions that, although the character of the doctors attached to the mission could be established, it would be impossible to apply a similar test to other members of the mission and thus guard against the presence amongst them of disguised officers. There is no prohibition against the dispatch of such missions from Egypt to Tripoli by land.

The Milk Bill.

Mr. EDWARD WOOD asked the President of the Local Government Board on what date it was proposed to introduce the Milk Bill.—Mr. BURNS answered: I am not yet able to fix a date for the introduction of the Bill, but I hope it may not be long deferred.

Improper Literature Bill.

Sir HILDRED CARLILE asked the Home Secretary whether he proposed to introduce this session his Bill dealing with improper literature, and whether time would be allotted to it in the Government programme.—Mr. MCKENNA replied: I propose to introduce this Bill and I hope that time may be found to pass it.

Mr. WEDGWOOD: Does the Government propose to set up a censorship of books as well as of plays?—Mr. MCKENNA: No; it is not proposed to censor anything.

MONDAY, FEB. 26TH.

Milk Preservatives.

Mr. STANIER asked the President of the Local Government Board whether mystin, used as a preservative for milk, was allowed under the regulations of the Board; and whether it contained sodium nitrate, and was therefore a danger to a person consuming it.—Mr. BURNS replied: Draft regulations have been prepared by the Local Government Board prohibiting the addition of any preservative substance to milk intended for sale for human consumption. Notice of these regulations was given in the *London Gazette* of Feb. 22nd, in accordance with the provisions of the Rule Publication Act, 1893. I am advised that "mystin" contains sodium nitrite (not nitrate), and that this is a drug with a powerful physiological action.

Foreign Milk and Tubercle Organism.

Mr. TOUCHE asked the President of the Local Government Board whether he could say approximately what proportion of the fresh milk imported from abroad was examined bacterially in regard to tubercle, and how long it took to examine a sample, and had any tubercle been found in the samples reported on in recent months.—Mr. BURNS answered: During the last five months of last year 50 consignments of fresh milk were imported. Forty-three samples were examined bacteriologically, but in no case was the tubercle organism found to be present. A conclusion that the organism is absent is not arrived at until six weeks after the receipt of the sample.

Milk and Tuberculosis.

Mr. TOUCHE asked the President of the Local Government Board whether he had received and considered a report by Dr. Harris, the medical officer of health of the borough of Islington, submitted to the public health committee of that borough, with reference to the finding of the Royal Commission on Tuberculosis, that a considerable proportion of the tuberculosis of childhood was to be ascribed to infection with bacilli transmitted in the milk of cows; and could he say when legislation on the subject would be introduced with a view to dealing effectively with this evil.—Mr. BURNS said in reply: The report has been received and is being considered in connexion with the general question to which it relates. With regard to the last part of the question I may refer to the answer which I gave on Thursday last to the honourable Member for Ripon (Mr. E. Wood).

The Notification of Tuberculosis.

Mr. FRED HALL (Dulwich) asked the President of the Local Government Board whether it was the intention of the Local Government Board that notification of tuberculosis made under its recent Order should be communicated by the medical officers of health to the Metropolitan Asylums Board in the same way as other infectious diseases.—Mr. BURNS answered: The reply is in the negative.

Medical Attendance and the Insurance Act.

Sir PHILIP MAGNUS asked the Secretary to the Treasury whether the official lecturers appointed to explain the details of the National Insurance Act had been instructed to inform insured persons as to the conditions under which they could obtain, in cases of sickness, medical attendance from duly qualified practitioners; and whether, having regard to the fact that these conditions were not yet settled, he would consider the advisability of postponing the lectures now being provided at the public expense till such time as should enable the Commissioners to state whether and, if so, under what arrangements the members of the medical profession had expressed their willingness to coöperate in giving effect to the Act.—Mr. MASTERMAN said in reply: The official lecturers have been given careful instruction to explain the Act as it stands on the statute book. The Act allows alternatives in respect of medical benefit; either that it shall be given from a panel with free choice of doctors, or that alternative arrangements shall be made by the Insurance Committee or the Commissioners, or that medical benefit shall be suspended and the money equivalent returned to the insured person.

Official Lectures on the Insurance Act.

Sir PHILIP MAGNUS asked the Secretary to the Treasury whether Members of that House, medical practitioners, and medical students, to whom a knowledge of the details of the Insurance Act was of especial value, were or would be admitted to the lectures of the official lecturers.—Mr. MASTERMAN replied: If any body of medical practitioners or other persons affected by the Act apply for the attendance of an official lecturer, the Commissioners will be happy to consider their request.

The Transmission of Sleeping Sickness.

Dr. CHAPPLE asked the Secretary of State for the Colonies whether any additional evidence had been brought to his notice that game in Nyasaland was a reservoir, and Glossina morsitans a carrier, of the trypanosome of sleeping sickness; and whether, in view of the evidence so far available and the consequences of delay, fraught with peril to the natives, the whites, their domestic animals, and their trade, he would propose such a modification of the game laws as would enable those who suffered to drive off the game, and with it the tsetse fly, from the vicinity of villages and transport routes.—Mr. L. HARCOURT replied: I am in consultation with my expert advisers, the managing committee of the Sleeping Sickness Bureau, on the whole question, and I am not in a position to make any statement at present, but I can promise my honourable friend that there will be no avoidable delay. With regard to the latter part of my honourable friend's question, I would point out that under Section 19 of the Nyasaland Game Ordinance, 1911, any land-holder or his servant finding a protected animal doing damage to his holding may kill the same without a licence if such act is necessary for the protection of his holding, and that under Section 30 of the same ordinance, when it is shown that any wild animals are causing damage to any native, the resident of the district may authorise the tribesmen or inhabitants of the village to kill the animals. Any person would, of course, be allowed to drive away game from his holding.

TUESDAY, FEB. 27TH.

The Tuberculosis Committee.

Mr. EDWARD WOOD asked the Chancellor of the Exchequer whether any of the gentlemen appointed to the committee of inquiry into the problem of tuberculosis were professors of the veterinary profession; and if not, whether, in view of the intimate connexion of the problems of human and animal tuberculosis, he could see his way to add such representation to the committee.—Mr. LLOYD GEORGE: The answer to the first part of the question is in the negative. I will bring the honourable Member's suggestion before the Chairman of the Committee. In fact, I have already done so.

WEDNESDAY, FEB. 28TH.

Scottish Medical Insurance Commissioner.

The Marquis of TULLIBARDINE asked the Secretary to the Treasury why the Medical Commissioners appointed under the provisions of Section 52 (1) of the National Insurance Act must have had personal experience of general practice; whether there was the same proviso with regard to the Scottish Medical Commissioner, and, if not, would he say why a different course had been adopted; and whether the Scottish Medical Commissioner had had experience of general practice.—Mr. MASTERMAN said in reply: Sections 57 and 80 of the Act require that all the Commissioners must have among their members a duly qualified Medical Commissioner. In England only is experience of general practice a statutory condition of his appointment; but this condition, though not statutory, is also fulfilled by the Scottish Medical Commissioner.

The Marquis of TULLIBARDINE: Then this gentleman has experience of general practice?—Mr. MASTERMAN: Yes, many years' experience.

BOOKS, ETC., RECEIVED.

AMERICAN CLIMATOLOGICAL ASSOCIATION, Philadelphia. (Secretary, Dr. Guy Hinsdale, Hot Springs, Virginia, U.S.A.)

Transactions of the American Climatological Association. For the Year 1911. Volume XXVII. Price not stated.

MCGAVIN.—On Feb. 22nd, on board H.M.S. *Conway*, Cadet John Beauchamp McGavin, aged 13 years, only son of Mr. and Mrs. Lawrie McGavin, of 32, Weymouth-street, W.

MUNYARD.—On Feb. 22nd, at Villa Solaro, San Remo, Italy, Thomas Guillaume Munyard, L.R.C.P., L.R.C.S., aged 57 years.

OLIVER.—On Feb. 22nd, at 7, Ellison-place, Newcastle-on-Tyne, Emma Octavia, aged 58, wife of Sir Thomas Oliver, M.D.

YOUNG.—On Feb. 22nd, at Raynham-avenue, Didsbury, Lancashire, Alfred Harry Young, LL.D., F.R.C.S., aged 60, Emeritus Professor of Anatomy, Manchester University.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

A PORT AUTHORITY AND FOOD REGULATIONS.

THERE is no need to enlarge on the importance of every precaution being taken to protect our food-supply. We are exposed on every side to quite enough risks without having to fear as to the foreign goods which come into our ports. The tinned-meat scandals of five years ago are not forgotten, nor how, after revelations which profoundly affected the public mind not only in America but in England, Mr. Burns, with a full conception of his duty as the head of the Local Government Board, set to work to see what could be done to prevent their repetition. The outcome, it will be remembered, was the passing by both Houses of Parliament of the Public Health (Regulations as to Food) Act, 1907. There were two sets of regulations, one as regards foreign meat and the other as regards unsound food, and it is interesting to note that the Local Government Board has been taking steps to see that these regulations are being carried out. An inspector visited Newhaven in July last and found that the administration of the regulations in the port was not only unsatisfactory, but, as a matter of fact, that the report agreed upon following a conference which the inspector had with the officers of the port sanitary authority four months previously, in which was indicated the minimum amount of inspection necessary for carrying out the regulations in the district, had been seriously curtailed, with the result that a large and relatively important section of foreign foodstuffs was not being dealt with by the authority, while the inspection of coastwise traffic had been entirely suspended. The reason for this, the inspector ascertained, was in consequence of certain definite instructions of a confidential nature issued by the port sanitary authority to its officers. These were to the effect that as the medical officer was not given an increase of salary the authority informed him that he need not make any visits of inspection unless required by the inspector or customs official; and it appears from the discussion at the port sanitary authority meeting when the whole subject was ventilated, that the authority declines to increase the salary of its medical officer because of the extra duties on the ground that as the foodstuffs which come into the port are not for Newhaven but for the nation, the cost of carrying out the regulations should be borne by the Imperial exchequer. Thus because the Newhaven port sanitary authority has refused to discharge its obligations in this important matter by paying its medical officer an adequate remuneration the food-supply of London—for the vast majority of the cargoes arriving at the Sussex port goes to the metropolis—has been jeopardised. Newhaven may be a small place—its population at the last census was 6665, against 6772 in 1901—and composed entirely of the working classes, but that is no argument why the port sanitary authority declines to pay its medical officer more than £30 per annum to carry out what is probably the most important regulations issued from Whitehall within recent years. The inspection of imported foodstuffs at the port of discharge is the governing principle of the regulations, and the Local Government Board will see that the inspection is carried out in such a way as to secure the country against the introduction of unsound food of all descriptions. The port sanitary authority is taking up quite a defiant attitude in the matter, an attitude ridiculous in the extreme. The members must be aware it is absolutely essential that all authorities must carry out the regulations in the same spirit and with the same degree of uniformity, or it will be found that importers will direct their supplies to a port where a less stringent or no inspection at all is enforced. The town of Newhaven must benefit to some extent by the trade of the port, and if the port sanitary authority is so obsessed with the idea of economy that it is unable to breathe the atmosphere of sanitary advance, it had better take steps to have the port closed to all kinds of foodstuffs and foreign meat.

ROLLER SKATES IN THE STREET.

IT will probably have been noticed by many that the small boy who used to be a common object in our streets floundering along with a roller skate attached to one foot has recently been superseded and rendered inconspicuous by boys generally of a larger size, and no doubt of greater affluence, furnished with pairs of skates, and making vigorous if not expert use of them. The lad who contrived to slide along poised uncertainly on his one skate, and, punting himself about on the pavement with the other foot, was a comparatively harmless nuisance. He made a disagreeable amount of noise in a quiet street, and not infrequently he got in the way of pedestrians, but he made few enemies, and hardly deserved such reprobation as fell to his lot. Some people indeed used to pity him because he only had one skate, which suggested poverty, although others who claimed to be better informed explained that the police would interfere with the enjoyment of a pair, whereas they regarded the slow progress possible with one as harmless and negligible. Apparently this was a mistake. The police do not interfere with the use of pairs of skates in the street, and it is stated that the Home Office declines to instruct them to do so. Why this should be it is difficult to see. The public have a right to pass along the highway, and none to turn it into a place of amusement. They have also the right to proceed upon their lawful purposes without being interfered with and hampered by others who use the same thoroughfare improperly. Boys skating at full speed along the footway either regard it as a playground only, or if going from one place to another are doing so in a manner inconvenient to others. They are, in fact, not only a nuisance but a dangerous one. Intent upon their own amusement, they are not likely to make allowance for the slower movements or sudden hesitancies of the ordinary pedestrian, who, moreover, may be elderly and infirm. Roller skates carry no brakes, and collision in the case of the unskilful performer when once imminent is usually inevitable. If it takes place it may or may not be serious, but a fall upon stone pavement is not unlikely to result in a broken limb, and even when no fall takes place a foot armed with a heavy roller skate will inflict a kick more severe than most of us have experienced since our football days. Moreover, if nothing is done to put a stop to this dangerous and selfish amusement at an early stage of its development the number of its devotees will inevitably increase during the coming summer. As rinks become less popular, stocks of skates will come upon the market at a price that will suit the pocket of their only likely purchaser, the schoolboy, with the result that street-skating will become a popular pastime. Without, therefore, wishing to see the healthy amusements of the town-bred boy needlessly diminished, we may be excused for protesting against their being added to by the introduction of a new form of exercise inconvenient or dangerous to other members of the community.

A DISCLAIMER.

To the Editor of THE LANCET.

SIR,—In view of the accounts of the so-called "Miracle Case" which appeared in the papers during the past few days, I should like to make it quite clear that I am not responsible for any publicity that has been given to my name in connexion therewith.

I am, Sir, yours faithfully,

Seymour-street, W., Feb. 27th, 1912. EDWIN ASH.

THE HISTORY OF ST. GEORGE'S HOSPITAL.

IN THE LANCET of June 11th, 1910, and Jan. 21st, 1911, respectively we reviewed the first two parts of the "History of St. George's Hospital," remarking at the end of the second notice "that it certainly should appeal to all past and present students of St. George's Hospital," and that "the medical profession generally might like to learn the history of an institution associated for years with men like John Hunter, Edward Jenner, Matthew Baillie, Benjamin Brodie, and Thomas Young." No further part of this interesting work has yet been issued, and we notice, with regret, from a letter in the current issue of the *St. George's Hospital Gazette* that Mr. George C. Peachey, who undertook to write the book, has failed to receive the financial support which had been promised. Ill-health has added to his burden, but with praiseworthy courage he writes, "The one thing I am sure of is that the work will not be abandoned in my life-time." There should be many members of the medical profession and even of the lay public to subscribe to a work which adds to a neglected side of historical literature, and we feel sure that the labours of Mr. Peachey would be more fully appreciated and encouraged if the difficulties under which he is working were widely known.

PHARMACOLOGICAL RESEARCH.

WE have received from Messrs. Burroughs, Wellcome, and Co., Snow Hill Buildings, London, E.C., a series of reprints of the scientific papers contributed recently by the chemists of the Wellcome Chemical Research Laboratories to the Chemical Society. In the paper by Frederic B. Power, Ph.D., and Charles W. Moore, Ph.D., on the Constituents of Bryony Root, the authors conclude that the activity of bryony root cannot be attributed to a single definite principle, and that it would appear that its purgative property resides chiefly in the resinous and alkaloidal constituents. There is, further, no reason for assuming that the active principle is a glucoside. In a paper on the Constituents of Rhubarb, Mr. Frank Tutin and Mr. Hubert W. B. Clewer summarise the investigation by reporting that the percentages of the various substances actually present in rhubarb are as follows: Essential oil, 0·005; verosterol, 0·1; mixture of fatty acids, 0·31; cinnamic acid (free), 0·01; gallic acid (free), 2·2; rhein, 0·12; rheinolic acid, 0·003; emodin, 0·78; aloe-emodin, 0·16; emodin monomethyl ether, 0·22; chrysophanic acid, 0·49; non-glucosidic resin, 10·4; tannin, 0·52; crystalline mixture of glucosides of the anthraquinone derivatives, 2·0. Of the anthraquinone derivatives rhein, emodin, and emodin monomethyl ether were found to be devoid of purgative action, the first two compounds being quickly excreted in the urine. Aloe-emodin and chrysophanic acid were distinctly, although not very actively, purgative. The glucosides of the anthraquinone derivatives had a bitter, astringent taste, but were quite devoid of purgative action. One of the non-glucosidic resins had a prompt purgative action, 0·1 gramme causing a much more pronounced

effect than the same weight of aloe-emodin or of chrysophanic acid, although it represented a much smaller amount of the drug. In a paper on the Constituents of the Bulb of Buphane Disticha ("poison bulb," a native of South Africa, or the "gift bol," as the Dutch call it) the principal alkaloid found was not brucine, as has been asserted, but an amorphous base called buphanine, which resembles hyoscine in its physiological action. Another alkaloid—narcissine—is also present, but it is not very toxic. In a paper on the Constituents of the Seeds of Casimiroa Edulis, the authors—Frederic B. Power, Ph.D., and Thomas Callan, Ph.D.—conclude that there is no evidence of the presence of a definite glucoside, as has previously been affirmed, and physiological tests have failed to confirm the reputed hypnotic or toxic properties of the seeds. A note upon Casimiroa edulis appeared in THE LANCET of August 21st, 1909, p. 561, in which, on the authority of certain French investigators, it was stated that this Mexican plant had hypnotic and analgesic properties. Lastly, a paper on the Chemical Examination of Calabar Beans, by Arthur H. Salway, Ph.D., D.Sc., shows that the bean, in addition to some essential oil, resin, and other amorphous substances, contains physostigmine; physovenine, a newly recognised alkaloid which, like physostigmine, produces a powerful myotic effect on the pupil of the eye; eseramine, another alkaloid; and oils. No evidence was obtained of the presence in Calabar beans of the alkaloid "isophysostigmine" or of "eseridine," said to have been isolated by previous investigators.

VITAL STATISTICS OF THE EAST AFRICA PROTECTORATE.

THE annual report of the Governor, Sir E. P. C. Girouard, K.C.M.G., on the administration of the East Africa Protectorate has been received at the Colonial Office, and is to be presented to Parliament in due course. The territories comprised in the Protectorate have an area of approximately 200,000 square miles, and include the whole of the coast from Umba to the Juba River, granted on a 50 years' lease by the Sultan of Zanzibar, as also the vast territories in the interior bounded in part by international conventional lines. On the west the Protectorate adjoins that of Uganda. A great portion consists of pasture lands or barren wastes, but there are not lacking extensive districts of great natural fertility on the coast, as well as in the interior.

It is stated in the report that the public health during 1910 was more satisfactory than in the previous five years. The improvement resulted largely from weather conditions, a third year of scanty rainfall in succession having modified the courses of various diseases. The total numbers of patients attended to in the Government hospitals during the past three years were: In 1908, 90,712 (with 940 deaths); in 1909, 90,924 (1034 deaths); and in 1910, 89,044 (1110 deaths).

The decrease in cases was most noticeable in the blackwater and malarial admissions; of the latter there were over 1500 fewer, with 45 per cent. less deaths. The year was fortunate in that there was no particular outbreak of epidemic disease to record. Of the endemic diseases, small-pox and plague showed a considerable subsidence, while there was a continued existence of sleeping sickness, which is restricted to the shores of Lake Nyanza. Two diseases—tuberculosis and enteric fever—are on the increase, and though the number of recorded cases of the former is very small, there is the evidence of various medical missions, which are in closer contact with the native life of the country than is possible at Government dispensaries, that it is spreading. The bulk of the enteric cases occurred among Europeans, and from the list of localities to which the infection has been attributed it has a wide range. Before 1906 it was practically unknown. An increase in the number of cases of amœbic dysentery has also to be recorded. Of other diseases, those affecting the nervous system remained stationary. There was an increased number both of digestive and respiratory illnesses; the latter, however, showed a largely lowered death-rate compared with the previous year. A large number of local injuries were treated, with 50 per cent. less deaths. 3071 surgical operations were performed, with 9 fatalities, 2 more than last year out of 1547 operations.

In 1910 diseases of the nervous, respiratory, circulatory, digestive, and urinary systems, generative organs, and locomotory systems, &c., numbered 38 per cent. of the total admissions, or 35,742, with 298 deaths. 229 of these deaths were caused by respiratory and digestive ailments. General and local injuries amounted to 19,173 cases, with 20 deaths. The details as to insect-borne diseases were: sleeping sickness, 96 admissions and 22 deaths; plague, 8 and 4; dengue, 1 and *nil*; malaria, 11,205 and 50; blackwater fever, 10 and 5. The figures for the following diseases were: small-pox, 21 admissions and 8 deaths; enteric fever, 30 and 2; beri-beri, 32 and 1; tetanus, 4 and 3; tuberculosis, 49 and 7; syphilis, 1413 and 12; gonorrhœa, 978 and 1; leprosy, 5 and *nil*.

Alienist would be much obliged if any of our readers would kindly inform him what is the maximum daily quantity of thyroid extract it is safe to give to a young plethoric adult suffering from threatened dementia. He is at present taking each day eight of the 5 grain thyroid gland tabloids manufactured by Burroughs, Wellcome, and Co., each of which is supposed to be equivalent to one grain of the desiccated gland. Again, is it safe to continue this treatment indefinitely? An answer to the above queries by those having had experience of the above treatment in mental cases would greatly oblige.

Arthur.—There is no doubt that difficulty attends the sale of practices at the present moment. There is no great likelihood that the value of the appointments will decrease to such an extent, but should a successor obtain them he still runs a risk of not making in other directions the income which the practice has hitherto commanded.

Mr. W. G. Walford.—The friend who is quoted is not trustworthy. No one has commented upon the views here; and so far from the Listerian doctrines being ridiculed in THE LANCET all Lord Lister's early work was published in these columns, where the first account of the new methods and new system appeared.

A. E. H.—Our correspondent would seem to have entirely misunderstood the scope and results of the work of the pathologist to the Scottish Asylums.

J. S.—The address of the honorary secretary of the Association of Public Vaccinators is 1, Mitre-court-buildings, Temple, E.C.

Mr. Algernon Ashton.—In our notice of Lord Lister's career the error was not made.

J. G. (*Lancs.*) has, we consider, assumed too much.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced for March and April:—

March 7th–11th (Berlin).—Thirty-third Balneological Congress.
March 23rd–April 4th (London, Royal Agricultural Hall).—International Smoke Abatement Exhibition.
April 1st and 2nd (Milan).—Italian National Convention upon the Sexual Question.
" (London).—First Congress of Pure Food and Health Society of Great Britain.
" 1st–7th (Tunis).—Twenty-second Congress of French-speaking Alienists and Neurologists.
" 8th–13th (Rome).—Seventh International Congress of Dermatology and Syphilology.
" 8th–15th (Johannesburg).—Thirteenth South African Medical Congress.
" 9th–11th (Paris).—Congress of Physiotherapy for French-speaking Physicians.
" 9th (Berlin).—Eleventh Congress of the German Society for Orthopædic Surgery.
" 9th–13th (Giessen).—Congress on Study of Families, Inheritance, and Race Hygiene.
" 10th–13th (Berlin).—Forty-first Congress of the German Surgical Society.
" 14th (Berlin).—Eighth Congress of the German Röntgen Society.
" 14th–20th (Rome).—Seventh International Congress on Tuberculosis.
" 15th–18th (Wiesbaden).—Twenty-ninth German Congress for Internal Medicine.
" 21st–24th (Munich).—Twenty-sixth Meeting of the Anatomical Society.
" (London, Olympia).—Ideal Homes Exhibition.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

THE LANCET Office, Feb. 28th, 1912.

Date.	Barometer reduced to Sea Level and 32° F.	Direction of Wind.	Rain fall.	Solar Radio in Vacuo.	Maximum Temp. Shade.	Min. Temp.	Wet Bulb.	Dry Bulb.	Remarks.

The following journals, magazines, &c., have been received:—
St. Thomas's Hospital Gazette, St. George's Hospital Gazette, Medical Chronicle, Archives Internationales de Neurologie, Annales de Gynécologie et d'Obstétrique, Archives de Médecine et Pharmacie Navales, Bulletins et Mémoires de la Société Médicale des Hôpitaux de Paris, Malaria e Malattie dei Paesi Caldi, Zentralblatt für die gesamte innere Medizin und ihre Grenzebiete, Revista de los Hospitales, Revista Médica del Uruguay, Archivo Brasileiros de Medicina.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).

TUESDAY.

SECTION OF ANÆSTHETICS (Hon. Secretaries—Mrs. Dickinson Berry, H. J. Scharlieb, C.M.G.): at 5.30 P.M.

Joint Meeting with
SURGICAL SECTION and
MEDICAL SECTION.

Adjourned Debate:
On Partial Thyroidectomy under Local Anæsthesia, with Special Reference to Exophthalmic Goitre.

The Debate will be opened by Mr. A. E. Barker. The following will take part in the Debate:—Mr. Charters Symonds, Mr. Donald Armour, Mr. Walter Edmunds, Dr. J. Blumfeld, Mr. C. H. Fagge, Dr. H. J. Scharlieb, C.M.G., Dr. G. A. H. Barton, Mr. Rupert Farrant, Mr. H. J. Paterson, and Mr. James Berry.

PATHOLOGICAL SECTION (Hon. Secretaries—J. C. G. Ledingham, A. E. Boycott), at Pathological Laboratory, Royal Army Medical College, Grosvenor-road, S.W.: at 8.30 P.M.

Colonel W. H. Horrocks: Variability of the Typhoid Bacillus.
Major W. S. Harrison: Joint Culture in Rheumatic Fever.
Lt.-Col. Sir William Leishman: Further Observations on Tick Fever.
Major S. L. Cummins: Observations on a Typhoid Carrier.
Captain J. C. Kennedy: A Case of Actinomycosis.

WEDNESDAY.

BALNEOLOGICAL AND CLIMATOLOGICAL SECTION (Hon. Secretaries—A. Manuel, F. A. de T. Mouillot): at 5.30 P.M.

Paper:
Dr. Armstrong (Buxton): The Spa Treatment of Neuritis.

(After the meeting Members will dine together at Pagani's Restaurant, Great Portland-street, W., at 7 P.M. Price of dinner 3*s.* 6*d.* All Fellows and Members are invited to attend and bring guests. In order that proper arrangements may be made Members are requested to reply to the Hon. Secretaries of the Section, 15, Cavendish-square, W.)

THURSDAY.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION (Hon. Secretaries—J. H. Targett, W. W. H. Tate): at 8 P.M.

Specimens:
Dr. Lediard: (1) Extra-peritoneal Suppurating Dermoid; (2) Sacral Teratoma in an Infant Two Days Old—Operation and Recovery; (3) Large Warty Fibroma of Labium.
Dr. Briggs: (1) Large Placenta in Case of Ectopic Gestation Three Months Beyond Term; (2) Fibroid of Uterus of Unusual Character.
Dr. Clifford White: Fœtus with Congenital Hereditary Graves's Disease.

Short Communications:
Dr. Briggs: Cæsarean Section in a Case of Dystocia Due to Loops of Cord Round Fœtus at Term.
Dr. Fothergill: The Classification of Disease.
Dr. Glendining: Fibro-adenoma of the Ovarian Fimbria and the Question of Accessory Ovary.
Dr. Lockyer: Embryotomy after Version for Placenta Prævia.

(N.B.—On Friday, March 15th, at 8.30 P.M., Members are specially invited to attend the meeting of the Electro-Therapeutical Section, when Dr. Bordier (of Lyons) will read a paper on the Radio-therapeutic Treatment of Uterine Fibroma.)

FRIDAY.

GENERAL MEETING OF FELLOWS at 4.45 P.M.
Election of Candidates for Fellowship.

CLINICAL SECTION (Hon. Secretaries: James Galloway, Charles H. Fagge): at 8.30 P.M.

Demonstration of Cases:
Dr. Galloway: Case of Muscular Dystrophy.
And other Cases.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—9 P.M., Dr. A. E. Garrod: Glycosuria. (Lettsomian Lecture III.)

RÖNTGEN SOCIETY, City and Guilds Technical College, Leonard-street, City-road, Finsbury.

TUESDAY.—8.15 P.M., Demonstrations:—Prof. S. P. Thompson: Physiological Action of an Alternating Magnetic Field.—Mr. W. Hampson: Radiometer.

NORTH-EAST LONDON CLINICAL SOCIETY, Prince of Wales's Hospital, Tottenham, N.

THURSDAY.—4.15 P.M., Clinical Cases.

WIMBLEDON AND DISTRICT MEDICAL SOCIETY, Johnston's Rooms, 6, Broadway, Wimbledon.

FRIDAY.—9 P.M., Dr. G. P. Shuter: Anæsthetics

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

MONDAY, WEDNESDAY, AND FRIDAY.—5 P.M., Prof. A. Keith Important Phases in the Evolution of Man.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. H. MacCormac: Clinique (Skin). 5.15 P.M. Lecture:—Dr. F. W. Price: Showing Cases to Illustrate Lectures.

TUESDAY.—4 P.M., Dr. T. Thompson: Clinique (Medical). 5.15 P.M., Lecture:—Dr. G. E. Herman: Some Points in the Hygiene of Pregnancy.

WEDNESDAY.—4 P.M., Mr. P. Turner: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. A. F. Tredgold: Some Medical Aspects of Eugenics.

THURSDAY.—4 P.M., Mr. H. Lett: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. C. Riviere: The Action of Tuberculin and its Application to the Treatment of Different Forms of Tuberculosis.

FRIDAY.—4 P.M., Mr. H. T. Mant: Clinique (Ear, Nose, and Throat). 5.15 P.M., Lecture:—Dr. W. Wingrave: Cerebro-spinal Fluid.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 10.30 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12 noon, Dr. Bernstein: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. R. Lloyd: Administration of Anæsthetics.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 11 A.M., Mr. Etherington-Smith: Demonstration of Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Mr. Pardoe: Clinical (Urinary Surgery).

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 10.30 A.M., Surgical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M.. Dr. Simson: Diseases of Women. 5 P.M., Lecture:—Dr. Low: Insects as Carriers of Disease in Tropical Medicine.

THURSDAY.—10 A.M., Dr. Simson: Gynæcological Demonstration. 12.15 P.M., Lecture:—Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Baldwin: Practical Surgery. (Lecture VI.)

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 12.15 P.M., Lecture:—Dr. Pritchard: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Morton: The X Ray Diagnosis of the Digestive System.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. Bishop Harman: Diseases of the Eye. 10.30 A.M., Medical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10.30 A.M., Surgical Out-patient (Mr. E. Gillespie). 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham): Nose, Throat, and Ear (Mr. H. D. Gillies). 3 P.M., Clinical Pathology and Pathological Demonstration (Dr. W. H. Duncan).

TUESDAY.—Clinic; 2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld).; Surgical (Mr. Howell Evans); Gynæcological (Dr. A. E. Giles). 3.30 P.M., Medical In-patient (Dr. A. J. Whiting). 4.30 P.M., Lecture:—Dr. G. G. Macdonald: The Bacteriology of Catarrh.

WEDNESDAY.—Clinics:—2 P.M., Throat Operations (Mr. Gillies). 2.30 P.M., Children's Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen): Eye (Mr. R. P. Brooks). 3 P.M., X Rays (Mr. W. Steuart); Clinical Pathology and Pathological Demonstration (Dr. W. H. Duncan). 5.30 P.M., Eye Operations (Mr. Brooks).

THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 P.M., Medical In-patient (Dr. G. P. Chappel).

FRIDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld): Surgical (Mr. E. Gillespie); Eye (Mr. R. P. Brooks). 3 P.M., Medical In-patient (Dr. R. M. Leslie); Clinical Pathology and Pathological Demonstration (Dr. W. H. Duncan).

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4.30 P.M., Mr. R. Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

TUESDAY.—2 P.M., Operations. 3.15 P.M., Dr. R. Wells: Medicine. 2.15 P.M., Mr. R. Carling: Surgery. 4.15 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin. 2.15 P.M., Special Lecture:—Mr. Carling: Operations on the Heart and Vessels.

WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 4.30 P.M., Special Lecture:—Mr. Cantlie: Applied Anatomy.

FRIDAY.—2 P.M., Operations. 2.15 P.M., Sir J. Rose Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

SATURDAY.—10 A.M., Radiography. 11 A.M., Dr. A. Davies: Pathological Demonstration. 2 P.M., Operations. Out-patient Demonstration:—10 A.M., Surgical and Medical. 11 A.M., Eye.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

THURSDAY.—4 P.M., Lecture:—Dr. Langmead Cyclic Vomiting.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC. Queen-square, Bloomsbury, W.C.

TUESDAY.—3.30 P.M., Clinical Lecture:—Dr. F. Batten: Muscular Atrophy.

FRIDAY.—3.30 P.M., Clinical Lecture:—Dr. G. Holmes: Paths of Sensory Conduction.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.

TUESDAY.—6 P.M., Dr. W. K. Sibley: Syphilis.

THURSDAY.—6 P.M., Chesterfield Lecture:—Dr. M. Dockrell: Undiagnosed Syphilides.

UNIVERSITY OF LONDON (UNIVERSITY COLLEGE), The Francis Galton Laboratory for National Eugenics.

TUESDAY.—8.30 P.M., Mr. N. B. Harman: Some Signs of Physical Degeneracy and their Lessons. (Lecture VI.)

ANCOATS HOSPITAL, Manchester.

THURSDAY.—4.15 P.M., Dr. F. C. Moore: Treatment of Pneumonia. (Post-Graduate Clinic.)

MANCHESTER ROYAL INFIRMARY.

FRIDAY.—4.30 P.M., Mr. Rayner: Tuberculous Disease of the Spine and Hip, with Special Reference to Early Diagnosis.

SALFORD ROYAL HOSPITAL.

THURSDAY.—4.30 P.M., Mr. F. P. Buckley: Operative Treatment of Fractures. (Post-Graduate Course).

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (4th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), Central London Throat and Ear (Minor 9 A.M., Major 2 P.M.).

TUESDAY (5th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London, (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.), Royal National Orthopædic (9.30 A.M. and 4 P.M.).

WEDNESDAY (6th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's 2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

THURSDAY (7th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal National Orthopædic (9 A.M. and 3.30 P.M.), Royal Ear (2 P.M.), Children Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

FRIDAY (8th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Royal National Orthopædic (3.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.)., Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

SATURDAY (9th).—Royal Free (9A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.), Hospital operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

The Index and Title-page to Vol. II. of 1911 were given in THE LANCET of Dec. 30th, 1911.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1911 are now ready. Bound in cloth, gilt lettered, price 16*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

Communications, Letters, &c., have been received from—

A.—Messrs. Allen and Hanburys, Lond.; Messrs. Ayrton, Saunders, and Co., Lond.; Messrs. R. Anderson and Co.. Lond.; Aymard Patent Milk Sterilizer Co., Ipswich; Dr. Edwin Ash, Lond.

B.—Bishopstone House, Bedford, Superintendent of; Bristol Royal Hospital, Secretary of; Messrs. M. J. Breitenbach Co., New York; Burton-on-Trent Infirmary, Secretary of; British Aluminium Co., Lond., Secretary of; Messrs. C. Barker and Sons, Lond.; Mr. E. Baker, Birmingham; Mr. E. Bougault, Paris; Dr. A. Brown, Lond.; Professor F. A. Bainbridge, Stocksfield-on-Tyne; Messrs. Bale, Sons, and Danielsson, Lond.; Mr. H. Bazett, Burwell; Mr. W. H. Battle, Lond.; Messrs. P. Beiersdorf and Co., Lond., Manager of; Messrs. P. Blakiston's Son and Co., Philadelphia; British Medical Benevolent Fund, Lond.; Captain J. H. Brunskill, R.A.M.C., Curragh Camp; Dr. G. W. Badgerow, Lond.; Dr. A. T. Brand, Driffield; Sir Lauder Brunton, Bart., Lond.; Mr. G. Sherman Bigg, Lond.; Messrs. Baillière, Tindall, and Cox, Lond.

C.—Dr. R. H. Cole, Lond.; Mr. H. A. Collins, Croydon; Carlisle Non-Provident Dispensary, Hon. Secretary of; Cheltenham General Hospital, Secretary of; Cincinnati Medical Book Co., U.S.A.; Messrs. T. Christy and Co., Lond.; Messrs. Constable and Co., Lond.; College of Preceptors, Lond., Secretary of; Dr. Helen Chambers, Lond.; Colonial Office, Under-Secretary of State, Lond.; Dr. Harold Clifford, Manchester; Dr. Myer Coplans, Leeds.

D.—Messrs. S. Deacon and Co., Lond.; The Dioradin Agency, Lond., Manager of; Derby County Asylum, Mickleover, Secretary of; Mr. A. S. Downing, Albany, N.Y.; Messrs. Duncan, Flockhart, and Co., Lond.; Dorland Agency, Lond.; Messrs. W. Dawson and Sons, Lond.; Dr. Thomas Dutton, Lond.; Dorai.

E.—Electrical Engineering Co., Lond.; Miss Edgar, Wokingham; Dr. W. d'Este Emery, Lond.

F.—Messrs. Fletcher, Fletcher, and Co., Lond.; Messrs. Fannin and Co., Dublin; Mr. F. A. M. Flegg, South Woodford; Mr. H. Finnemore, Lond.; Major H. C. French, R.A.M.C., Valetta; Mr. W. H. Furness, Philadelphia, U.S.A.; Dr. W. E. Fielden, St. Helier; Dr. H. P. Fairlie, Glasgow; Dr. W. E. Fothergill, Manchester; Dr. John Fawcett, Lond.

G.—Mr. G. H. Gemmell, Edinburgh; Galen Manufacturng Co., Lond.; Mr. A. S. Gregory, Birmingham; Gloucestershire Royal Infirmary, Gloucester, Secretary of; Dr. A. E. Garrod, Lond.; General Register Office, Dublin; Dr. A. S. Grünbaum, Lond.; Professor Dr. Galli, Bordighera; Mr. J. Good, Blackrod; Glasgow Medico-Chirurgical Society, Secretary of; Dr. Edwin Goodall, Cardiff; Sir Walter Gilbey, Bart., Lond.

H.—Messrs. W. H. and A. G. Herbert, Lond.; Mr. T. H. Hewitt, Lond.; Dr. M. G. Hannay, Lond.; Messrs. C. J. Hewlett and Son, Lond.; Dr. N. Hannah, Ashton-in-Makerfield; Mr. C. W. Hutt, Grappenhall; Hastings, Town Clerk of.

I.—Messrs. Isaacs and Co., Lond.; Income-Tax Recovery (Briant's) Agency, Hastings.

J.—Mr. W. Judd, Lond.; *The Journal of Nervous and Mental Disease*, New York.

K.—Messrs. H. S. King and Co., Lond.; Dr. Knight, Edinburgh; Kensington Dispensary, Lond., Secretary of; Mr. J. Knopf, Lond.; Dr. O. Kraus, Paris; King Edward's Memorial Hospital, Lond., Hon. Secretary of; Messrs. H. Kendall and Sons, Lond.; Mrs. Kirby, Lowestoft; Mr. Dudley Kennard, Lond.; Dr. Robert Knox, Lond.

L.—London Press Exchange, Lond.; Mr. H. K. Lewis, Lond.; Loughton Urban District Council, Clerk of; Mr. F. W. Lowndes, Liverpool; Mr. J. Bernard Lamb, Lond.; Dr. G. H. Lancashire, Withington; Dr. Thomas D. Lister, Lond.; Liverpool, Medical Officer of Health of; Dr. T. Glover Lyon, Ashtead; Leeds and West Riding Medico-Chirurgical Society, Secretary of; Dr. W. Lauzun-Brown, Lond.; Mr. R. Clement Lucas, Lond.

M.—Macclesfield General Infirmary, Secretary of; Dr. J. A. Müller, Negri Sembilan; Mr. R. Mosse, Berlin; Messrs. J. Maclehose and Sons, Glasgow; Mr. G. Mowat, Saxmundham; Mr. G. B. Messenger, Sheffield; Medical Correspondence College, Lond.; Maltine Manufacturing Co., Lond.; Captain R. McCarrison, I.M.S., Lond.; Dr. S. G. Moore, Huddersfield; Mr. G. N. Morton, Glasgow; Middlesex Hospital Medical School, Lond., Dean of; Dr. Paul Mayer, Lond.; Medical Sickness and Accident Society, Lond., Secretary of; Mr. J. Penn Milton, Yelverton; Mr. R. H. G. Marquis, Lond.; Midland and Western Counties Obstetrical and Gynæcological Society, Birmingham, Hon. Secretary of; Mr. F. Milton, Ramsgate.

N.—Mr. J. C. Needes, Lond.; Mr. H. Needes, Lond.; Newcastle-under-Lyme Corporation, Clerk to the; Nithsdale Dairy, Edinburgh; Nottingham General Dispensary, Secretary of; National Medical Union, Manchester, Secretary of.

O.—Dr. Bernard O'Connor, Lond.

P.—Dr. A. C. Parr, Feltham; Dr. R. W. C. Pierce, Guildford; Mr. D'Arcy Power, Lond.

Q.—Queen Charlotte's Lying-in Hospital, Lond., Secretary of.

R.—Royal Victoria Hospital, Dover, Secretary of; Royal Portsmouth Hospital, Secretary of; Messrs. Rebman, Lond.; Radcliffe Infirmary, Oxford, Secretary of; Royal Orthopædic Hospital, Birmingham, Secretary of; Rotherham Hospital, Secretary of; Royal Ear Hospital, Lond., Secretary of; Royal Institution of Great Britain, Lond.; Radnorshire Education Committee, Llandrindod Wells, School Medical Officer of; Dr. Guthrie Rankin, Lond.; Dr. T. Lettsomian Lectures
ON
GLYCOSURIA.

Delivered before the Medical Society of London.

BY ARCHIBALD E. GARROD, D.M., M.A. OXON., F.R.C.P. LOND., F.R.S.,

PHYSICIAN TO, AND LECTURER ON CHEMICAL PATHOLOGY AT, ST. BARTHOLOMEW'S HOSPITAL; PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN.

LECTURE III.*

Delivered on March 4th.

MR. PRESIDENT AND GENTLEMEN,—When we enter upon the study of the internal secretions, and of the effects of disease in the glands which produce them, we find ourselves in one of the wonderlands of physiology and medicine. It behoves us to move with caution and to plant our footsteps firmly as we go, for the path is narrow and slippery, and on either side of it lie the swamps of fallacy and the mists of unrestrained hypothesis.

It is only in comparatively recent years that we have come to learn anything of the functions of the ductless glands, but, once started, progress has been rapid. We are beginning to appreciate the disturbances produced in the organism by excessive or diminished activity of certain individual glands of the group, and especially of the thyroid, and to trace indications of correlation of functions and interaction of these organs; of mutual inhibition in some cases and of coöperation in others.

Hence we are able to realise that a clinical picture which is presented when one of the glands of internal secretion, ductless or other, is diseased, may be due, not only to restricted or excessive production of the secretion of the diseased gland, but also to an upsetting of a natural balance of functions, due to a withdrawal of the stimulus or restraint which it exerts upon other members of the group. Such is the idea which underlies the use of the term polyglandular syndrome, which is often heard in the present day. Thus, removal of the thyroid leads to enlargement of the pituitary gland, and when the thyroid is over-active the thymus tends to undergo hypertrophy, to quote only two out of a number of known examples of interrelation.

Unquestionably these glands of internal secretion exert profound hormonic influences upon the metabolic processes carried on in the organism. When the thyroid is over-active the metabolic fires burn too brightly; when its activity is suspended they burn low; and the influence of internal secretions upon carbohydrate metabolism in particular admits of no question.

Nor must we omit to mention the influence exerted by the ductless glands upon bodily development—an influence which is clearly manifested in acromegaly, and more clearly still in diseases which develop during childhood. It is seen in the arrested bodily and mental growth of the cretin, in the precocious obesity and hirsuties induced by some tumours of the adrenal cortex, in the obesity and infantilism which constitute Fröhlich's syndrome, and in the precocious puberty associated with tumours of the pineal gland.

However, it is with the influence of the ductless glands upon carbohydrate metabolism that we are at present concerned.

GLYCOSURIA AND THE THYROID GLAND.

That exophthalmic goitre, the symptom-complex which results from hyperthyroidism, is sometimes associated with diabetes has long been known, as witness the cases recorded by Dumontpellier[1] in 1869, by Brunton[2] in 1874, by Wilks[3] in 1875, and by O'Neill[4] in 1878; and more recently it has been shown that the lowering of tolerance of glucose is not uncommon in association herewith.

Observers differ as to the frequency of such alimentary glycosuria e saccharo in Graves's disease. Undoubtedly in many cases no diminution of tolerance can be detected, but my own experience leads me to take my stand with those who hold that it is by no means an uncommon phenomenon. In not a few cases spontaneous excretion of sugar, of a transitory or intermittent kind, is observed, if carefully watched for, and in others, as I have already mentioned, persistent glycosuria, with the usual attendant symptoms which go to make up the clinical picture of diabetes. Thus we find the three grades of disturbed carbohydrate metabolism, to which I have so frequently referred, all represented among cases of exophthalmic goitre.

In some cases I have seen glycosuria follow so small a dose of glucose as 20 or 30 grammes and in a larger number 100 grammes sufficed to produce that effect. For example, a girl, aged 18, was admitted to hospital suffering from exophthalmic goitre. Her urine, passed after admission, was found to contain traces of a reducing substance which was proved to be glucose. This did not recur. At a later period a dose of 100 grammes of glucose was given at 11.30 A.M.; the urine passed at 1.30 P.M. contained 0 29 per cent. glucose, a specimen passed at 4 P.M. contained a mere trace, and subsequent specimens were sugar-free. In some cases the test dose of glucose has been followed by a glycosuria which has persisted for several days, as if the patient were actually on the verge of spontaneous excretion of glucose.

In the cases in which transitory spontaneous glycosuria occurs the output of sugar tends to be small—under 1 per cent.; it may be present on a single day only, or on several successive days, or it may recur at intervals. This phenomenon suggests that the tolerance is habitually so low that it is occasionally overstepped on an ordinary diet, and is in accord with the statement of H. Strauss,[5] that in the majority of conditions in which alimentary glycosuria e saccharo is wont to be met with spontaneous glycosuria is not infrequently seen.

The following case, which may be included in the diabetic group, exhibited several features of peculiar interest.

A coal porter, aged 33 years, was admitted to St. Bartholomew's Hospital under my care on May 9th, 1911. In his family asthma was the only hereditary complaint. At the beginning of April his wife had noticed that his eyes were staring, and at the same time he began to suffer from shooting pains in the occipital region, which were usually worst in the early morning. He tired more easily than usual and noticed that his heart beat unusually quickly at times. He had lost 5 lb. in weight during the preceding five weeks. His eyes were markedly protuberant and staring. There was retraction of the upper lid, and von Graefe's sign was well seen; convergence was natural, and his forehead became wrinkled when he looked upwards. There was conspicuous fine tremor of the hands, and his emotional and restless state tended to confirm the diagnosis of Graves's disease. However, his thyroid gland was not obviously enlarged. The area of cardiac dulness was normal and no murmur was heard, and although he had noticed palpitation at times his pulse-rate was only 60 on his admission, full and regular, with a systolic tension of 112 mm. His urine contained a reducing substance, which was proved to be glucose, to the amount of 0·06 to 0·38 per cent. on different days. The carbohydrate of his diet was reduced, and he was kept completely at rest, but he at no time had less than 6 oz. of bread a day during his stay in hospital. His pulse remained slow rather than quick—80 per minute was the quickest rate recorded, and on two occasions the rate fell as low as 48. Nevertheless, his appearance and symptoms as a whole left no doubt as to the diagnosis. Dr. J. G. Priestley, who examined his urine and fæces, reported that Cammidge's reaction was negative, and that the total fat amounted to 26·9 per cent. of the dried fæces, 7·4 per cent. being saponified, and 19·5 per cent. unsaponified fat. The patient improved conspicuously under treatment. The eyes became less prominent and the tremor diminished, and the sugar in his urine was reduced to a trace. However, he was restless, and would not consent to stay after May 23rd. When he was next seen, on June 2nd, his thyroid was distinctly enlarged and the pulse-rate was 100.

On July 10th the patient was readmitted and stayed until July 22nd. The eye symptoms were as before; the enlargement of the thyroid was slight; his pulse-rate was 92 on

* Lectures I. and II. were published in THE LANCET of Feb. 24th (p. 483) and March 2nd (p. 557), 1912, respectively.

[5] Deutsche medizinische Wochenschrift, 1897, Band xxxiii., p. 309.

admission, and a systolic murmur was audible over the base of the heart. The restlessness and excitability had become aggravated. The urine contained from 0·36 to 0·55 per cent. sugar, and from 6·7 to 11·45 grammes were excreted in the 24 hours. The largest quantity of urine passed was 3180 c.c. in 24 hours. His weight had decreased by a further 4 lb. On two occasions the thyroid was exposed to the X rays; but the excretion of sugar was not influenced by this treatment. At this time Dr. Cammidge was good enough to examine the urine and fæces, and reported that the urine gave only a very doubtful pancreatic reaction by the distillation method, but none by the fermentation method. Although the total fat in the fæces was not very high, he found that the unsaponified exceeded the saponified fats, and this fact, coupled with incomplete casein digestion, he regarded as indicating the presence of a pancreatic lesion. The man was again seen on Sept. 6th, when the exophthalmos was less pronounced. A specimen of urine contained 0·25 per cent. glucose. Since that date we have unfortunately lost touch with him.

The most remarkable feature in this case was the variation of the pulse-rate and the bradycardia which was a prominent feature during his first stay in the hospital.

In most cases of diabetes occurring in association with exophthalmic goitre there is good reason to believe that the onset of the two groups of symptoms is more or less simultaneous, or that the symptoms of Graves's disease have preceded the glycosuria. However, we must not lose sight of the possibility of the development of the thyroid symptoms in patients who are already diabetic, a sequence of which a striking example is mentioned by Grube,[6] that of a woman who developed exophthalmic goitre after hearing that her urine contained 9 per cent. sugar. Moreover, accidental concurrence is also possible in connexion with this as with other conditions, but the evidence of the association of glycosuria with lesions of any special organ is not based upon their occasional concurrence alone, but rather upon the evidences of interdependence of the symptoms in individual cases. The diabetes of hyperthyroidism runs no exceptional course, the output of sugar may be large, and all the ordinary associated symptoms, culminating in death in coma, may be present.

I must not omit to mention that some observers have called attention to families in which Graves's disease has been present in some members and diabetes in others, and I myself have seen a young woman suffering from the severest form of diabetes whose mother had exophthalmic goitre.

Glycosuria Induced by Thyroid Administration.

We can hardly doubt that the excess of thyroid secretion is the exciting cause of the glycosuria in the disease under discussion, for lowering of glucose tolerance and spontaneous excretion of sugar may be induced by the medicinal use of thyroid extract. This fact has not received so much attention as it deserves, although it was noticed by Dale James,[7] Béclère,[8] and others, as long ago as 1894, and it affords an additional reason for caution in the use of that drug. I have recently seen sugar appear in the urine of a youth aged 18, who probably had no thyroid inadequacy, after he had taken 5 grains of thyroid extract daily for about six weeks. When the drug was stopped the glycosuria promptly ceased.

My own experience leads me to think that, as might be expected, this result is more readily brought about in cases in which thyroid secretion is normal, and the extract given acts as an overdose, than in those in which it is deficient or absent. Thus, in another case, in which the drug was given to reduce obesity, sugar appeared in the urine to the amount of 4 per cent. at the end of a week, when only 4 grammes had been taken in all, but quickly disappeared after the treatment was stopped.

However, patients with myxœdema may acquire glycosuria in this way. My house physician, Mr. Alan Moore, was good enough to examine the urine of 11 myxœdematous patients who had been under thyroid treatment in the out-patient department at St. Bartholomew's Hospital for years. No less than four were found to have glycosuria, and in three cases the excretion of sugar ceased within a week after the thyroid was stopped.

Ewald[9] has recorded a remarkable case of a myxœdematous woman who acquired glycosuria on three successive occasions after the administration of thyroid extract in very moderate doses, such as one 5-grain tablet a day, as much as 5 or 6 per cent. of sugar being present in her urine. In the intervals the urine was sugar-free.

In Notthaft's[10] most remarkable case, that of a man, aged 43, who, on his own initiative and in order to reduce his weight, took about 1000 5-grain tablets of thyroid extract in the course of five weeks, glycosuria was induced; but in association with it there appeared the other symptoms of Graves's disease—tachycardia, exophthalmos with von Graefe's sign, tremor, and even some enlargement of the thyroid gland. He passed over 3000 c.c. of urine in the day, which contained sugar to the amount of 1 per cent. Apart from any limitation of carbohydrates, the sugar disappeared and thirst ceased after the drug had been discontinued for ten days. Tremor ceased after four weeks, but the eye phenomena and swelling of the thyroid persisted for about six months.

It has been thought that in some instances administration of thyroid has given rise to actual diabetes, and von Noorden suggests that in such cases a pre-existent diabetic tendency has been awakened into activity by the drug. Friedrich von Müller[11] has described the onset of a rapidly fatal diabetes in a sufferer from exophthalmic goitre who was treated with thyroid extract, but here the treatment may have merely precipitated an event to which the original disease was itself capable of giving rise. If spontaneous hyperthyroidism can induce diabetes one sees no reason why continuous thyroid treatment should not do the same.

How the Thyroid Gland Influences Carbohydrate Metabolism.

It is a question of much theoretical interest whether or no the thyroid gland produces its effect upon carbohydrate metabolism through the pancreas. Opie inclines to the view that the glycosuria of Graves's disease is due to an associated pancreatic lesion, and such lesions have been found in some fatal cases. Thus, R. C. Cecil[12] quotes a case in which the pancreas was small and atrophic. The fact that thyroid administration may produce glycosuria can only be reconciled with such an explanation if we suppose that the hyperthyroidism produces the lesions of the pancreas, and some cases recorded by Dr. George Murray[13] strongly suggest that even when exophthalmic goitre is recovered from it may leave behind it irreparable damage to the pancreas.

Falta[14] suggests, on the other hand, that the excess of thyroid secretion exercises a check upon the function of the pancreas, either directly or by stimulating the activity of the chromaffin system. In favour of the latter explanation he refers to the observations of Kraus and Friedenthal and of A. Fränkel, who detected an increase of adrenalin in the blood of patients with Graves's disease, but emphasises the necessity of caution in such speculations. Falta has also extended the observations of A. Schmidt and Salomon,[15] on the occurrence of fatty stools in exophthalmic goitre. Their occurrence suggests a coincident restriction of the external secretion of the pancreas, and so favours Opie's view, but both Falta and Salomon found no such excess of neutral fats as is characteristic of pancreatic steatorrhœa, and the fat absorption was not markedly aided by administration of pancreon. Falta refers to certain observations which suggest that the internal, as well as the external, secretion of the pancreas is concerned in fat absorption. However, as he pointed out, serious difficulties are encountered when we attempt to explain the fatty stools of exophthalmic goitre by invoking a restraining influence exerted upon the internal secretion of the pancreas, not the least of which arises from the absence of fatty stools in most of the severe cases of ordinary diabetes.

If hyperthyroidism tend to induce glycosuria by exercising a restraining influence upon the functions of the pancreas, rather than by causing lesions of that gland, we should expect that withdrawal of the normal supply would have an opposite effect, and that the pancreas, relieved of its wonted restraint, would be unusually active in relation to carbohydrate metabolism. In other words, that an individual who formed no thyroid secretion would be able to deal with

larger quantities of carbohydrates than a normal person. This appears to be the case, for a number of observers have found that patients with myxœdema exhibit a conspicuously raised glucose tolerance, and can take with impunity far greater amounts of sugar than would inevitably induce glycosuria in an ordinary man. Moreover, when thyroid extract is administered a lowering of glucose tolerance is induced. Thus, in the case of a boy, aged 6, recently under my care, who showed signs of hypothyroidism, but was not a complete cretin, 150 grammes of glucose were required to induce glycosuria, but after a short period of thyroid treatment, 50 grammes sufficed to produce excretion of sugar. Some adult patients with myxœdema seem able to dispose of any dose of glucose which can be given without excreting any of it. A similar elevation of glucose tolerance has been observed in dogs deprived of their thyroid glands, although a transitory glycosuria, perhaps due to emptying of the glycogen reservoirs, may follow the operation.

To sum up, then, it would appear that, whatever the mechanism called into play, excess of thyroid secretion tends to induce glycosuria, whereas hypothyroidism has an opposite effect. However, these effects are by no means constant, and whereas some patients who exhibit the other signs of thyroid excess in a marked degree do not excrete sugar, and may show no lowering of glucose tolerance, in other cases of a less pronounced kind glycosuria is one of the earliest symptoms manifested. The cause of this uncertainty of behaviour is not obvious, but, as we have seen, it is a feature common to most varieties of glycosuria.

Myxœdema with Excretion of Glucose.

On the other hand, we cannot shut our eyes to the existence of certain paradoxical cases, which appear to stand in direct contradiction to what has gone before. In these cases patients who were apparently suffering from myxœdema, or at least from thyroid insufficiency, have excreted sugar, apart from treatment by thyroid extract. The subject has been discussed at some length in a recent paper by Parisot.[16]

In some of the records, which are few in number, it is merely mentioned that a slight glycosuria was observed on one or more occasions. In other cases there has been some hesitation as to the diagnosis, and there have been peculiar features which justify the doubt whether, in spite of marked improvement under thyroid treatment, and in some instances disappearance of the glycosuria under such treatment, the disease from which the patient suffered was really myxœdema, and not rather disease of some ductless gland other than the thyroid, or possibly of more than one such gland. Thus, a case which Sir William Osler described was one of those in which some features of hyper- and some features of hypo-thyroidism were present side by side.[17]

A. Gordon[18] described two little brothers, aged 3 and 4 years respectively, who had pronounced glycosuria and signs of myxœdema, apparently acquired. Under thyroid treatment the symptoms, including the glycosuria, disappeared, but in spite of a relapse which followed an interruption of treatment for three weeks in its earlier stages, there was no return of myxœdema or glycosuria after the thyroid extract was stopped some months later. The length of immunity is not stated, but it would appear necessary to assume a temporary hypothyroidism in these cases.

I am indebted to Miss Heanley for the notes of a case, hitherto unpublished, which resembled Gordon's in this respect. The patient was an unmarried woman, aged 25, who suffered from amenorrhœa of 12 months' standing, and a swelling of the whole body, with headache and hystero-epileptic attacks. She is described as having a red, bloated face, with coarse red whiskers, and a well-developed moustache. Physical examination revealed nothing beyond an enormous increase of subcutaneous tissue. Her hands had become dry and clumsy and she became depressed and stupid, but her speech was never slow nor indistinct. Her urine had a specific gravity of 1040, and contained much sugar. She took thyroid extract in large doses, which in a month were reduced to five grains daily in consequence of signs of hyperthyroidism. Four months later, when the drug was stopped, her general health had greatly improved, her fatness was reduced, and the depression had disappeared. The urine no longer contained sugar. Although she had had no further thyroid treatment since May, 1908, when seen in November, 1911, she had a thin face and thin hands, the hair on her face was much diminished, and she was quite well. The urine was sugar free.

One can hardly class this case as one of myxœdema, and the hirsuties and obesity rather suggest the syndromes associated with tumours of the adrenal cortex and of the pineal gland; but with neither of these latter has glycosuria hitherto been observed. Miss Heanley and the patient were both convinced of the efficacy of the thyroid treatment, and whatever its nature, the case is of great interest as an example of temporary glycosuria associated with symptoms suggestive of a temporary affection of one or more of the glands of internal secretion.

A case recorded by Dr. W. M. Campbell[19] in 1894 was also that of a young woman, and the diagnosis of myxœdema was confirmed by the late Dr. Ord. She improved greatly on thyroid treatment, but the glycosuria persisted and was thought by Dr. Campbell to have been influenced by dieting rather than by thyroid extract.

Granting that glycosuria does occasionally accompany myxœdema, this fact cannot be held to invalidate the mass of evidence which connects that symptom with hyperthyroidism and various explanations of the paradox suggest themselves. For example, the supposed control of the thyroid over the pancreas, and the converse over-activity of the pancreas when this control is removed, will not come into play if the pancreas be itself diseased. Again, it is conceivable that, seeing that removal of the thyroid leads to hypertrophy of the pituitary body, the secretion of the latter gland may contribute to the causation of glycosuria in these cases; and again that the parathyroids may be concerned, for Eppinger, Falta, and Rudinger[20] found that removal of the parathyroids of a dog tends to depress glucose tolerance to a conspicuous degree.

GLYCOSURIA AND THE PITUITARY BODY.

Like the thyroid gland, the pituitary body has a very important influence upon the metabolism of carbohydrates, and in this connexion there is a striking resemblance between the effects of diseases of these structures.

Acromegaly is now believed to represent the syndrome which results from over-activity of the glandular portion of the pituitary, and thus to be the pituitary analogue of exophthalmic goitre. As in exophthalmic goitre, we meet in some cases of acromegaly with lowered glucose tolerance; in others with transitory or intermittent glycosuria; and in yet others, with frank diabetes. Indeed, if we may judge from the relative frequency of such symptoms in acromegaly and gigantism on the one hand, and in Graves's disease on the other, we should incline to regard hyperpituitarism as a more potent disturber of carbohydrate metabolism than hyperthyroidism.

Thus, Borchardt,[21] who collected the records of 176 cases of acromegaly, found that glycosuria had been observed in 63 cases, or no less than 35·32 per cent. In eight other cases lowered glucose tolerance had been noted, but that symptom had obviously been much less frequently looked for, and was only mentioned, as present or absent, in ten cases in all.

In some cases the glycosuria of acromegaly has been little, if at all, influenced by restrictions of diet, whereas in others it was so controlled. It is interesting to note that in the newer literature of pituitary tumours, since 1886, Borchardt found no record of glycosuria apart from acromegalic symptoms.

It is a peculiar feature of acromegaly glycosuria that in some cases the excretion of sugar has ceased completely, for a period, although the patient's diet was by no means poor in carbohydrates. Thus Strümpell[22] carefully watched, over several years, a case in which the urine of 24 hours contained at times as much as 100 to 120 grammes of glucose, and polyuria and thirst were prominent symptoms. During two separate periods, with an interval of four years between them, the sugar disappeared completely in spite of a diet rich in carbohydrates. In yet other instances the glycosuria, after persisting for years, has ceased and has not returned.

Borchardt quotes such a case from Lichtheim's Klinik, and Pineles refers to a similar case observed by Finzi.[23]

One is tempted to connect such occurrences with variations in the activity of secretion of the pituitary gland, and such lasting cessation of glycosuria may mark the point of time when, as Cushing holds, the hypersecretion, which causes the acromegalic changes, gives place to hyposecretion; just as in some instances myxœdema has developed as a sequel of exophthalmic goitre.

The group of symptoms, commonly spoken of as "Fröhlich's syndrome" or "dystrophia adiposo-genitalis," is believed to result from hypopituitarism. The group includes excessive deposition of fat, hypoplasia of the genital organs, and disappearance of axillary and pubic hair, associated with symptoms of tumour of the pituitary gland, somnolence, headache, and bitemporal hemianopia. In association with this condition glycosuria is almost unknown, although thirst and polyuria are common. Von Frankl-Hochwart,[24] in his monograph upon the subject, mentions its occurrence in only one case, and, as in myxœdema, a conspicuous rise in glucose tolerance has been observed.[25] This is confirmed by the most important studies of Goetsch, Cushing, and Jacobson[26] on the relation of the pituitary body to carbohydrate tolerance. These observers show, from their experimental investigations upon animals, that the posterior lobe of the pituitary is that which controls carbohydrate metabolism, and that its secretion is discharged into the cavity of the third ventricle, and thence passes into the subarachnoid spaces and enters the blood stream by way of the dural sinuses.

Their experiments demonstrate clearly that excess of the secretion of the posterior lobe entering the circulation has a conspicuous effect in lowering glucose tolerance, whereas deficiency of such secretion has an equally conspicuous effect in raising the limit of tolerance. The authors quoted state, further, that in all but two of the ten cases of acromegaly which they had studied the patients had begun to show evidences of hypoplasia of the posterior lobe, such as the laying on of fat, subnormal temperature, and, in some instances, remarkably high glucose tolerance. They suggest that, when such symptoms develop, administration of glandular extract is indicated, and that it may be possible to determine the correct dosage by ascertaining the quantity of glucose required to induce glycosuria, and by giving such doses of the glandular extract as reduce the glucose tolerance to the normal limit.

As regards the production of glycosuria by administration of pituitary extract, no such bulk of evidence is forthcoming as of its production by thyroid preparations. This is not to be wondered at, seeing that pituitary extract has been so much less widely used, and in view of Cushing's results, such an effect is only to be looked for from extract of the posterior lobe. Borchardt caused excretion of sugar in rabbits by injection of hypophysis extract, but in dogs the effect was very uncertain. I know of no case in which glycosuria has been observed in man to result from pituitary treatment.

In some cases of acromegaly, as in some cases of exophthalmic goitre, structural lesions of the pancreas have been met with. Thus Cecil[27] records a case in which sclerosis and hyaline degeneration of the islands of Langerhans were found, and Hansemann[28] has observed sclerosis of the pancreas in a case of acromegaly. However, Borchardt states that in most cases the pancreas has been found to be normal.

It seems probable that whatever be the mechanism by which hyperthyroidism induces lowered glucose tolerance and glycosuria, a similar mechanism may be invoked to explain the same phenomena when they accompany hyperpituitarism.

ADRENAL GLYCOSURIA.

When we pass on to the consideration of the part played by the adrenal glands in the causation of glycosuria, we find ourselves confronted with a still more difficult and complex problem.

There can be no question that adrenalin—the one hormone produced by a ductless gland, of which the chemical composition and nature are accurately known—has a very definite influence upon carbohydrate metabolism. How far that influence is at work in the production of glycosuria and diabetes, as seen in man, is uncertain, but there are indications that it may play a very important part. Thus the observation of André Mayer,[29] which has been confirmed by other investigators, that after the removal of the adrenals in rabbits puncture of the glycosuric centre no longer causes excretion of sugar, suggests that puncture glycosuria, to which I have so often referred, is due to the conveyance of an impulse to the adrenals by way of the splanchnic nerve and a resultant over-secretion of adrenalin.

Adrenalin is the secretion of the medullary or chromaffin tissue of the adrenals, and of the chromaffin tissues in general, of which the adrenal medulla constitutes only the major part. It is probable that the adrenal cortex yields a different internal secretion which has a profound influence upon nutrition and development, and which is responsible for the obesity and hirsuties seen in connexion with adenomatous tumours of that portion of these glands.

There is no evidence which suffices to carry conviction that gross lesions of the adrenals are to be included among the causes of clinical glycosuria. It is true that a very few cases are on record in which diabetes has been associated with adrenal tumours. Such cases have been described by Burghart[30] and by Lépine.[31] Burghart's patient was a woman who suddenly developed thirst and polyuria some three months before her death. Her urine contained as much as 8 to 10 per cent. of sugar, and a large sarcoma of the left adrenal was found post mortem. Lépine's patient, a woman aged 60, who also had a sarcoma of the left adrenal, had hyperglycæmia and glycosuria, and died in coma soon after her admission to hospital. There was a history of loss of flesh for two years, and of excessive thirst for a year and a half before her death.

It would be very rash to conclude on the basis of these cases that there exists a form of diabetes due to disease of the adrenals, for their rarity makes an accidental association highly probable and the evidence of the interdependence of the tumour and the glycosuria is of the slightest. It is at least probable that in Lépine's case the diabetes antedated the malignant growth. Malignant growths originating in the adrenal medulla are not uncommon in children, and I have seen a number of such cases, but in none of them did the urine contain sugar, nor was there a raised pulse tension to suggest an excess of adrenalin in the blood.

In Addison's disease a condition of hypo-adrenalism may be assumed to exist, and glycosuria is therefore not to be expected. It is interesting to note that Porges[32] has shown that the blood of sufferers from this malady is poorer in sugar than normal blood, and he confirms the observation of Eppinger, Falta, and Rudinger[33] that such patients exhibit an abnormally high sugar tolerance. In a case recorded by Dr. Samuel West,[34] in which the adrenals were completely atrophied and the skin was pigmented, there was a severe form of diabetes. Here excess of adrenalin is out of the question, but the case is of special importance as showing that a patient, deprived of his adrenals by disease, may nevertheless be diabetic. Unfortunately, no information is forthcoming as to the condition of the pancreas and other viscera in this case.

As Blum was the first to show, injection of adrenalin in doses of from 1 to 2 milligrammes excites a transient glycosuria, and I have recently seen such glycosuria in a case of asthma, in which such an injection was given for therapeutical purposes. The dose required to induce an excretion of sugar varies in different cases, and in sufferers from different diseases. A number of observations bearing on this subject have been made of recent years, and the results so far obtained are summed up in a recent paper by M. Reichenstein,[35] who is himself a worker in this field, and has studied the effects of injections of adrenalin in cases of Graves's disease, diabetes, a variety of nervous disorders, and during pregnancy.

It is evident that, given a disease which induces an excessive supply of adrenalin to the blood, hyperglycæmia and glycosuria are likely to be among its symptoms, and the evidence forthcoming suggests that adrenalin may play the chief part in regulating the glucose contents of the blood. In this connexion it is worthy of note that Ernst Neubauer [36] has detected hyperglycæmia in patients with chronic renal disease and high pulse tension, and that other observers have demonstrated hypertrophy of the chromaffin tissues and hyperadrenalism in such cases. It is possible at least that some of the cases of mild diabetes in later life may have their origin in a more pronounced degree of adrenalin excess.

GLYCOSURIA IN PREGNANCY.

A place must undoubtedly be assigned to pregnancy among the causes of glycosuria, but in approaching the consideration of this subject it must be borne in mind that lactosuria of slight degree is not uncommon during the last weeks of gestation, and that women suffering from diabetes occasionally become pregnant. Therefore it is necessary to make sure, in any given case, that the sugar excreted is not lactose, and also, what is more difficult to prove, that the glycosuria has only developed after the commencement of pregnancy.

Far more common than a spontaneous excretion of sugar is a lowering of glucose tolerance, and, as von Jaksch and his assistant, Lanz,[37] pointed out, in 1895, many pregnant women exhibit glycosuria e saccharo. This observation has since been fully confirmed. Bar[38] estimated that whereas in normal adults the limit of glucose tolerance is between 9 and 13 grammes per kilogramme of body weight, in pregnant women it is lowered to 6 to 8 grammes per kilogramme. Reichenstein, to whose work on adrenalin glycosuria I recently referred, found that the ease with which adrenalin caused glycosuria varied with the glucose tolerance.

The frequency of spontaneous glycosuria in pregnancy is very differently estimated, and the figures given probably depend largely upon the delicacy of the tests employed. As the excretion of sugar may be very transient, it is liable to be overlooked unless a careful watch is kept for it throughout the whole period of gestation. In his valuable paper on the subject, Whitridge Williams[39] quotes a case in which glycosuria, with excretion of 0·5 to 1 per cent. of glucose, began three months before labour and persisted for three weeks. Reichenstein[40] states that of 93 pregnant women, 11 (11·8 per cent.) excreted glucose to the amount of 0·2–0·7 per cent., usually in the eighth to tenth months. Of 65 patients, 27·6 per cent. excreted from 2 to 7 grammes after a dose of 100 grammes of glucose.

In a number of cases glycosuria which has begun during pregnancy has ceased after delivery, and in some such cases the quantity of sugar has been somewhat large, and thirst and polyuria have been prominent symptoms. Thus, in a case described by Durieux[41] thirst was complained of in the seventh month, and sugar was then first found at the weekly examination of the urine. The output was as much as 210 grammes in 24 hours, but after the diet was restricted it fell to 50 grammes, and after delivery it disappeared entirely. Cases of like kind were described by Bennewitz,[42] whose paper I have not seen, as long ago as the year 1826, and are referred to by Matthews Duncan in his classical paper which first awakened wide interest in puerperal diabetes, and whose gloomy conclusions as to the prognosis of diabetes in pregnant women have ever since dominated professional opinion on the matter.

Still more interesting are the cases in which diabetic symptoms have recurred in successive pregnancies, although absent in the intervals between them. Such cases show clearly that during pregnancy conditions exist which are favourable to the development of glycosuria, and which cease with its termination. This is in full accord with the observations on lowered glucose tolerance.

However, it cannot safely be asserted that a glycosuria which ceases after delivery is of necessity a merely temporary one, as is shown by a case for permission to quote which I am indebted to [illegible] Herringham. Bartholomew's [illegible] The daily output o[illegible] After her delivery o[illegible] but a glucose test some[illegible] was not fully restored. [illegible] readmitted, under Dr. [illegible] 60 grammes of glucose in [illegible] disappeared with a restricted [illegible]

Again, there are cases on r[illegible] diabetes has apparently commenced during pregnancy and has continued after delivery. In some of these coma has occurred during the puerperium. I cannot quote the record of any case in which glycosuria definitely shown to have first appeared during pregnancy, and in which after her delivery the patient lived on as a confirmed diabetic.

Several views have been put forward as to the [illegible] the glycosuria of pregnancy. Some have held with Williams that it is due to a toxæmia. Others, among whom Commandeur and Porcher,[44] connect it with abnormal metabolism associated with lactation, for glucose is a constituent of the disaccharid lactose.

The most recent theory, advanced by Reichenstein,[45] Cushing,[46] and others, ascribes the glycosuria of pregnancy to the influence of that state upon the glands of internal secretion, such as the thyroid and the pituitary body. In its clinical aspects this variety of glycosuria certainly bears a striking resemblance to those connected with diseases of the ductless glands, and it is on that account that it has been spoken of in this lecture. Enlargement of the thyroid gland during pregnancy is a well-known event, and changes in the pituitary have been shown by Erdheim and Stümme[47] to be common in that state. Such an explanation will account for the so frequent cessation of the glycosuria after delivery, and is at least highly plausible.

Moreover, it gains much support from a most interesting case which Marek[48] has very recently placed on record. The patient, a primipara, aged 26, developed the characteristic symptoms of acromegaly during the eighth month of pregnancy. Her hands and feet enlarged, her skin, nose, and lips were thickened, and enlargement of the lower jaw prevented her teeth from meeting. She became very somnolent. Sugar was present in her urine. After delivery the glycosuria ceased in about two months, and by that time all the signs of acromegaly had also disappeared. It can hardly be doubted that the glycosuria and attendant symptoms were alike due to hyperpituitarism developed in association with the pregnancy.

One naturally associates with the glycosuria of pregnancy that which has been observed in association with diseases of the female generative organs. Imlach[49] described a case in which removal of the uterine appendages, on account of pyosalpinx with ovarian adhesions, was followed within a week by cessation of glycosuria which had been detected five months before the operation and which was accompanied by thirst and polyuria. In cases recorded by Croom,[50] Beyea,[51] and Henkel[52] removal of ovarian tumours or uterine myomata has in like manner been followed in the course of a few months, and apart from restriction of diet, by disappearance of sugar from the urine. In Beyea's case the glucose amounted to as much as 7 per cent. It will be noticed that in most cases the cessation of the glycosuria has been much more gradual than after childbirth.

GLYCOSURIA WITHOUT HYPERGLYCÆMIA.

The last variety of glycosuria of which I propose to speak differs from all those which we have hitherto considered in one essential respect—namely, that the excretion of sugar in the urine is not dependent upon any excess in the blood.

In my first lecture I referred to the glycosuria which follows the injection of phloridzin, and it is the generally

The daily output ...averag... ...luenced by diet, was neither increased by a diet ...deter... ...to carbohydrates, nor diminished by restriction of starch. ...so large a dose of glucose as 100 grammes had no effect ...on the output. The blood serum was found to contain 0·097 per cent. of glucose, whereas 0·1 per cent., or rather less, may be taken as the normal content.

In Weiland's three cases the average quantity of sugar in the urine of 24 hours was 7–10 grammes, 3 grammes, and 10–20 grammes respectively. In no case was the sugar of the blood above the normal amount.

I have myself had opportunities of observing, for several years past, the case of a lady between 30 and 40 years of age who was found to be excreting sugar in 1907, but who has at no time exhibited any symptoms of diabetes. Some analyses made in India in 1907 and 1908 gave a daily output of about 1 gramme of glucose. The patient was placed upon a diabetic diet, but did not bear it well. On such a diet the output of sugar was, if anything, greater than when no restrictions were imposed. Soon after I first saw her, in 1909, she stayed in a nursing home for a time, and during that period the accompanying analyses were made by Dr. W. H. Hurtley, who employed Ivor Bang's method for the elimination of sugar.

[55] Ibid., 1910, Band xxxvi., p. 1031.
[56] Deutsches Archiv für klinische Medizin 1911, Band cii., p. 167.

It will be seen that the output of sugar is comparable to that in Bönniger's and Weiland's cases, and that restriction of diet, on the one hand, and the administration of a small dose (10 grammes) of glucose on the other, had no obvious effect upon the glycosuria. The great discrepancy, here seen, between optical activity and reducing power was also noticed by Weiland in one of his cases, and is not uncommon when very small quantities of glucose are present in urine. In this case glucose was definitely proved to be present, but even when the urine was lævo-rotatory lævulose was not detected, and the lævo-rotation was not destroyed by fermentation with yeast, but was actually increased owing to removal of glucose.

The patient was advised to avoid sugar and any great excess of starchy foods, but otherwise to take an ordinary diet. Her health remains good, and the last analysis on the table, made two years and four months later than those of the 1909 series, shows that in that interval there had been no aggravation of the glycosuria. Unfortunately, no estimation of the sugar in the blood has been made in this instance.

As long ago as in 1896 G. Klemperer[57] suggested that there probably exists a variety of glycosuria met with in clinical practice which is due to failure on the part of the kidneys to retain the normal sugar content in the blood. Such glycosuria would be of like nature to that caused by the administration of phloridzin. The cases which I have quoted have been regarded as examples of such renal glycosuria. No other explanation can be offered of an excretion of sugar which is not influenced by changes in the amount of carbohydrate in the diet and is not dependent upon any excess of sugar in the blood.

It would appear that in these cases the mechanism for dealing with carbohydrate is intact, nor can they be explained by deficient destruction, or excessive production, of sugar in the organism. However, it will be prudent to adopt an expectant attitude as to their explanation until further observations have extended our knowledge of this variety of glycosuria and until longer periods of watching have shown what is the ultimate outcome of such cases.

It is not suggested that the kidneys are the seats of structural disease, but rather of a functional disorder which may possibly be due to the presence in the blood of some endogenous or enterogenous toxin which acts in the same way as phloridzin does.

CONCLUSIONS.

And now the time at my disposal is almost exhausted, and I must endeavour to gather up the threads of my discourse and discuss very briefly the bearings of the matters dealt with upon the nature and treatment of diabetes.

In the course of these lectures I have called your attention to many different morbid conditions which bring about disturbances of the metabolism of carbohydrates and to the fact that such disturbances manifest themselves in several different ways: now by a lowering of glucose tolerance without actual excretion of sugar in the urine; now by a spontaneous excretion of sugar in smaller or larger amount during limited periods of days, weeks, or months; and now by a persistent glycosuria, accompanied in its higher grades by the associated symptoms which go to make up the clinical picture of diabetes. Moreover, we have seen how disturbances of these several grades may be induced in different cases by one and the same cause, or in the same case at different times.

The effect of this is to obliterate in one's mind the conception of diabetes as a sharply defined disease, and to present the malady as merely the maximal phase of a series, rising by gradual steps from the normal of metabolism, just as myxœdema is the culminating point of the almost insensible grades of hypothyroidism. Between the sufferer from grave diabetes and the potential glycosuric there is a striking contrast, but the gulf which separates them is bridged over by intermediate cases of all degrees of severity. If so, it follows that, with the possible exception of the so-called renal glycosuria, there is no such thing as non-diabetic glycosuria, although there are many varieties which lack the sinister import which we connect with the name of diabetes.

The differences are, I believe, rather of degree than of kind. In saying this I do not wish to imply that a transient glycosuria is necessarily of grave import, but rather that diabetes is not of necessity a fatal malady.

[57] Verhandlungen des Vereins für innere Medizin, 1896, Band xvi., p. 67.

We are beginning to realise that many organs take part in the regulation of carbohydrate metabolism, and that, if I may be allowed to change the metaphor previously employed, the displacement of one prop may endanger the equilibrium of the whole fabric. For it seems to me that we are justified in regarding the normal metabolic level as maintained by the balance of a number of mutually controlling forces.

In some instances the lesion of one of the supports of the fabric is capable of repair, and with its restitution the disturbance ceases and the normal condition is restored. In other instances the damage is beyond repair, and in time brings down the whole structure. We may imagine that in some individuals, as the result of inborn peculiarities, the equilibrium is less stable than in the majority, is upset by more trifling causes, and when upset is less easily restored. These are the people who inherit or possess the diabetic tendency.

Even when one of the props is removed the structure, although weakened, may still stand erect, and hence perhaps the uncertain incidence of glycosuria, even when the causes which tend to induce it are at work.

If such a conception in any way represents the truth it is clearly our business, in any case with which we meet, to seek to find out where the primary weakness lies, and to attempt its repair. In theory this is well enough; it is in its practical application that the difficulty is encountered.

Whilst it is true that in some cases of diabetes the nervous system is evidently at fault, and that in others the thyroid, the pituitary, or the pancreas is the seat of disease, in the great majority of cases which we encounter in practice we can find no indications of the underlying lesion upon which the metabolic derangement depends. The various tests of pancreatic efficiency give uncertain or negative replies; no ductless gland is evidently the seat of disease; no intestinal disturbance points to an origin in the alimentary tract, and no cardio-vascular changes help us to class the case. There is, to all appearance, a sheer, wanton, metabolic insanity. Nevertheless, we can hardly doubt that in such cases there is an underlying morbid cause at work, if only we could find it out, and that if we follow up minutely every clue and every deviation from the normal we shall surely see light in time. I for one do not believe that the chemical processes in the body go wrong of themselves.

Of course, it by no means follows that the detection of the underlying cause in any given case of diabetes will enable us to cure the patient. It is highly probable that in most instances the primary lesion is not amenable to treatment, either medical or surgical. Nor is it to be expected that any one plan will prove beneficial in all cases; the multiplicity of causes of the malady excludes any such hope. But that in the future the range of efficient control will be greatly extended I firmly believe, and I look forward to a time when the outlook of some diabetic patients at least will be far less hopeless than it is at present.

The efficacy of restriction of diet, which has ameliorated the lot and prolonged the lives of hosts of sufferers from diabetes, although it is essentially a symptomatic therapy, is due to the fact that it is the metabolic derangement which proves fatal to most such patients. Yet there is a growing dissatisfaction with the limitations of such methods, which can only postpone, and cannot avert, the fatal ending.

Only when we have learned more of what lies behind the diabetic syndrome can we hope to attain to better therapeutic methods. Then will our present dietetic treatment be relegated to its true position as a valuable means of holding in check the metabolic error and minimising its evil effects, whilst our main efforts are directed to the repair of the underlying lesions, so far as they admit of repair.

INTERNATIONAL EUGENIC CONGRESS.—As already announced an International Congress on Eugenics will be held at the University of London from July 24th to 30th, under the presidency of Major Leonard Darwin. An exhibition of charts and objects bearing on human heredity will be held in connexion with the Congress, and the secretary of the exhibition, 6, York-buildings, Adelphi, London, W.C., requests the loan of any objects relative to the subject.

ON

MALIGNANT DISEASE OF THE TESTICLE, AND THE OPERATION FOR REMOVAL OF THE ILIO-LUMBAR LYMPH-GLANDS WHEN SECONDARILY AFFECTED,

OR AS A PRECAUTIONARY MEASURE AT THE TIME OF EXCISION OF THE ORGAN PRIMARILY DISEASED.

BY SIR HENRY MORRIS, BART., M.A., M.B. LOND., F.R.C.S. ENG.

IN an interesting lecture on "An Improved Method of Removing the Testicle and Spermatic Cord for Malignant Disease," by Mr. J. Bland-Sutton, published in THE LANCET of Nov. 13th, 1909, reference is made to a case of mine which Mr. A. G. R. Foulerton had included in his well-known paper on "Chondrifying Carcinoma," published in the fifth volume of the Archives of the Middlesex Hospital (1905). Foulerton's account gives particulars of my case down to 1896. After reading Mr. Bland-Sutton's lecture I was induced to set in order my various notes and the several letters and telegrams I had at different times received concerning this patient, and these bring the complete history of the case down to the date of his death in 1904.

It so happened that in December, 1910, another patient, whose history is also one of long duration, came under my care; and this case caused me to make malignant disease of the testis the subject of one of my clinical lectures at the Middlesex Hospital in 1911. Other calls upon my time have prevented me hitherto from publishing this clinical lecture as I intended to do; but I am now moved to record the notes of the cases by the appearance in the columns of the last three successive issues of THE LANCET of (1) Mr. H Morriston Davies's article, (2) Sir Alfred Pearce Gould's letter, and (3) the letter and illustration of Mr. Bland-Sutton.

The first case which I shall describe is quite an extraordinary one. It is altogether exceptional, in its duration, course, complications, and the manner of the patient's death; and the operation performed for the removal of the secondarily involved abdominal lymph gland was spoken of by the late Mr. T. Nunn as the most extensive and severe operation he had ever witnessed. The histological picture presented by the sections of the abdominal mass removed from my patient accords precisely with that yielded by the lymph gland removed from the anterior surface of the inferior vena cava in Mr. Bland-Sutton's case.

CASE 1. *Clinical history.*—Captain ——, aged 28, married, was admitted at the request of the late Mr. Thomas Nunn under my care into the Middlesex Hospital on March 25th, 1895, on account of a large tumour in the left side of the abdomen. He had had his left testis removed in 1893 in India for what was described as an adeno-sarcomatous tumour. Up to that time his health had been good; but since, he had never been really well and had been frequently under treatment for neurasthenia and dyspeptic troubles, obstinate constipation, and twitchings and tinglings in his hands and feet. One month before his admission, it was stated, he had been under Mr. (now Sir) Victor Horsley, and it was then, it seems, that the abdominal tumour was first detected. It appears to have been regarded as an enlarged spleen, and was situated "higher up and further out" than at the time of admission to the Middlesex Hospital.

When first seen by me the patient's abdomen was not distended, but on palpation a large mass was felt below the costal margin on the left side. This mass extended nearly to the middle line, outwards under the tenth costal cartilage, and downwards to a line drawn horizontally on the level of the umbilicus. The tumour moved downwards slightly on deep inspiration. There was tenderness on deep pressure over the swelling and the percussion note over it was resonant. Splenic dulness was normal.

The operation.—An operation having been decided on, an incision was made (March 29th, 1895) through the abdominal wall along the median line from the ensiform cartilage to the umbilicus. As the growth was found to be situated behind the peritoneum the patient was turned upon his right

side, and a long oblique incision parallel to the last rib was made in and prolonged forwards and downwards from the left lumbar region. The tumour was in front of the kidney and was spread over the side and front of the vertebral column. With the fingers of one hand in the peritoneal cavity, and those of the other hand passed through the lumbar wound the mass could be made to move readily in a lateral direction. It was punctured posteriorly, but proved to be solid on this aspect. Complete enucleation from behind could not be effected, so the anterior incision in the abdominal wall was connected with another which transversely divided the left rectus muscle. An assistant then pressed forward the tumour with his fingers in the lumbar wound, the overlying peritoneum on the front of the tumour was divided, and together with some adherent small intestine was detached; and in this way the anterior surface of the tumour mass was exposed. A cyst, the size of an orange, presented itself; sponges were packed around this, and from the cyst, which was ruptured in the steps of the enucleation, turbid fluid escaped. When the separation was completed the tumour was extracted through the lumbar incision. After the main mass had been extracted, two smaller growths were detected and removed. A considerable length of the aorta was exposed. After irrigating with hot water, the wounds were closed. The patient made a satisfactory recovery, and was discharged on April 19th, just three weeks after the operation.

Naked eye appearances of the growth.—The growth removed consisted of three masses; the largest was roughly oval in shape, measuring 4 by 2½ inches, and was 2 inches in thickness. The two smaller masses were rounded, and each was about the size of a small orange. Their outer surfaces were smooth but irregular, the irregularity being caused by numerous small cysts. In the large mass there was an empty irregular cyst, 1 inch by 1½ inches in diameter, with a smooth inner lining to its walls. On section each mass was seen to have a definite fibrous-looking capsule and to contain numerous smaller cysts, varying in size from a pea to an olive. Some of the cysts contained clear fluid, but the greater number held a yellowish-brown gelatinous substance, on removing which other smaller cysts were seen projecting from the inner walls. The tissue between the cysts varied in amount in different places and had a fleshy appearance.

Microscopical appearances.—Microscopically the cystic spaces were lined by columnar epithelium, but from some of the larger spaces the epithelial lining had entirely disappeared. The homogeneous material which filled the spaces stained very imperfectly. The tissues between the spaces consisted of a very cellular fibro-cellular stroma in which were seen spindle cells, round cells, and cells with large oval nuclei. Mr. John Murray paid great attention at the time to the microscopical examination, and had kept by him sections which he was able to produce on the occasion of my clinical lecture last year. Mr. Foulerton included this case in his account of columnar-celled carcinoma of the testicle, and remarked that although the formation of cartilage was not observed, there was present the mucoid or myxomatous change in the fibrous stroma which is a stage preliminary to the development of cartilage.

Subsequent history.—On July 10th, 1895, Captain —— returned complaining of constipation, and stating that without taking medicine he could get no action whatever of the bowels for several successive days. He was readmitted and was ordered a senna draught and a little blue pill and colocynth. He remained three days in hospital, during which his bowels acted regularly and freely every day. He returned to India and took up his duties as a soldier, but in 1897 he was again back in England, invalided home on account of chronic constipation and abdominal pains. He was in a very neurotic state. On May 30th, 1897, he entered a nursing home and I opened his abdomen and separated numerous adhesions between different coils of intestine, and between the small intestine and the parietal peritoneum, as well as between the omentum and parietes in front. The omentum was dragging on the transverse colon, pulling it downwards. The patient made an easy recovery, except for a small sinus in the line of the scar, which healed at once after a deep suture escaped on July 15th, 1897. He again returned to India and resumed his duties. I had seen him in 1899, and have notes of two or three consultations in the autumn of that year when he as usual complained of abdominal pains; but I could not detect any abdominal tumour. At some time between this date and March, 1901, but exactly when is unknown to me, he was operated upon in India for "acute intestinal obstruction," and a large growth was found within the abdomen which it was impossible to remove. He recovered from the exploratory operation and the intestinal obstruction and was immediately invalided home. When I saw him on his arrival in 1901 I could find no abdominal tumour; in fact, he seemed in better condition than I had usually seen him, and after staying in England until the beginning of January, 1902, he again went back to India. He, however, subsequently came to England on invalid leave, and I saw him several times from April onwards in 1903, as he was home for six months in that year. At this time he was drugging himself with morphia; he always complained more or less of dyspeptic troubles—flatulence, intestinal distension, griping pains, and obstinate constipation. He had suffered in the same way before he underwent any abdominal operation, and he was always very neurasthenic; but these symptoms were more pronounced some time after the first operation than ever before, though they were greatly relieved by the detachment of adhesions in May, 1897.

Further and final report of the case from Indian medical officers.—On Nov. 23rd, 1904, Captain E. J. O'Meara, F.R.C.S.Eng., I.M.S., wrote to me as follows:—

"Captain —— came under my care in March or April, 1901, for acute intestinal obstruction. The abdomen was opened" by Colonel Joubert, "but it was found impossible to deal with the growth on account of its large size. Shortly after this the patient was invalided home, but returned after a few months very angry with me; as he said that you, after consultation with Mr. Watson Cheyne, told him that there was nothing the matter with him" (i.e., that there was no tumour so far as we could detect). "I also saw remarks by you on the case in the *Clinical Journal* about April, 1902. The growth must have diminished very rapidly indeed after the operation in 1901, as at the time of the operation it practically filled the abdomen. I enclose Captain Birdwood's letter; it will doubtless be of interest to you."

The remarks referred to in Captain O'Meara's letter as having been made by me about the case were published in the *Clinical Journal* of March 19th, 1902, in the report of a discussion on the treatment of inoperable cancer at the West London Medico-Chirurgical Society. I was calling attention to the fact that cases are from time to time condemned by competent and able clinicians as inoperable cancer which from their subsequent course would seem not really to have been malignant at all; and I was giving instances of such which had come under my own observation. In alluding to Captain ——'s case as that of an "Indian military officer," I said: "In the beginning of the year 1901 his abdomen was opened in India on account of obstinate constipation, and the wound was closed, as the surgeons found a condition which they reported to be malignant, and inoperable; and he was sent home to England to die. The mass found by these surgeons was, I believe, nothing more than the condensed and matted adhesions following the former operations; at any rate, this officer has just lately (January, 1902) returned to his duties in India fitter than he had done for some years."

My only informant about the operation which had recently been performed upon him in India was the patient himself. I had received no report of it from the surgeon who had performed it, or from anyone else who was present at the operation. Had I possessed an authoritative account of the operation I should, no doubt, have spoken of the case as one of those remarkable, rare, but attested instances in which a malignant tumour has spontaneously vanished, either after, or independently of, an operation. The sceptical tone of my remarks at the time, however, serves to show how completely the tumour had shrunk or vanished, as it was absolutely impossible of detection on the most careful palpation and percussion. Moreover, two years after the discovery in India of this large inoperable tumour Captain —— told me when in England in 1903 that he was contemplating a second marriage. He was feeling well enough to deem himself justified to take this step; and I have in my possession a telegram and a long letter sent to me from India by him in May, 1904, in reference to this projected marriage.

But the end was not so very far off. The marriage did not take place for reasons immaterial in this connexion. When Captain O'Meara wrote to me on Nov. 23rd, 1904, he enclosed a letter from Captain G. T. Birdwood, I.M.S., written

to Colonel C. H. De La Ferte Joubert, I.M.S., on Oct. 7th of the same year, which runs:—

"You will be sorry to hear that Captain —— died the day before yesterday. The operation was apparently successful, for next day he passed a very large motion. Colonel Barratt made a post mortem. There was a tumour the size of a cocoanut growing from the spine, with numerous adhesions in every direction matting down the intestines. The gut immediately behind the tumour was gangrenous, and packed with hard fecal scybalæ. The anastomosis must have taken place from a coil just above the gangrenous portion to a coil below the tumour. If the gut had not been gangrenous he might have lived a month or two, but the growth was increasing so rapidly that the end would not have been far off. As you had previously operated upon him I thought you would like to know how the case ended."

Colonel Joubert himself adds this comment to Captain Birdwood's letter:—

"The growth was about that size, or larger when we operated in 1901, and I felt it so big when I was in Agra in July last. Birdwood operated to relieve obstruction, and made an anastomosis. It has been a very irregular case for years past.—C. H. J."

No information is given as to the nature of the "tumour."

CASE 2.—In December, 1910, Mr. ——, aged 46, engaged in mercantile business in Calcutta, consulted me on account of pyuria and coli bacilluria. He told me that about 12 years ago he had undergone castration for a tumour of the right testicle. Whilst he was under my treatment I received a letter from Dr. Adrian Caddy, F.R.C.S., of Calcutta, dated Feb. 1st, 1911, from which I abstract the following:—

"We are writing to you concerning a patient of ours, Mr. ——, who has been under our care for several years past. My brother, Dr. Arnold Caddy, removed Mr. ——'s testicle for chondro-carcinoma of that organ about ten years ago. I may say that he published the case in the 'Annals of Surgery' at the time. Since that time Mr. —— has kept in good health until June last, when he developed a long-continued fever of a typhoid character which lasted several weeks, and which he had when he was put on board a ship for England. After about three weeks of fever he developed pyuria, which I believe has lasted ever since; previous to his illness he had a gleet. We X rayed him and found nothing. A pathologist here found bacillus coli infection in his urine, and made a vaccine which, injected into him (the patient) unfortunately seemed to make him worse, and so was not persisted in at the patient's request; a guinea-pig was inoculated with urine but with negative results. ..... All the time we were fearing a late recurrence of the chondro-sarcoma, somewhere in the urinary tract, &c."

Disregarding the important and interesting subject of coli-bacilluria my reason for relating this case is because of its association histologically, pathologically, and clinically, with the subject of columnar carcinoma, or adeno-sarcoma of the testis, and thus with Case 1 just previously related. From the account in the "Annals of Surgery" of 1899 (Vol. II., p. 210) I have abstracted the following notes:—

In December, 1894, when Mr. —— was 29 years of age, he was struck in the right testis by a cricket-ball. Considerable pain at the time was followed in a week by some hardness of the lower end of the testicle. This hardness remained without change until October, 1895, when the testis began to enlarge, and the hardness to spread upwards. In September, 1896, the testis was the size of a duck's egg, painless, hard, and somewhat larger at the upper end than elsewhere. And so it remained, unaltered, until June, 1898, when the testis became painful and tender. A fortnight later the organ began suddenly to increase in size. On Dec. 17th, 1898, the testis was excised. It was the size of a closed fist. The spermatic cord was not thickened. No lymph glands could be felt.

On vertical section the whole mass appeared to be a new growth, no testicular tissue being apparent. At the upper and back part a nodule of cartilage the size of a nutmeg was cut through.

Microscopical appearances.—A microscopic examination was made by Major J. F. Evans, the professor of pathology at the Calcutta Medical College, who pronounced the growth to be a chondro-carcinoma. The cartilage was in the neighbourhood of the epididymis, and was surrounded and interrupted by many cysts lined by columnar epithelium. Professor Evans tells that the microscopic sections of this growth correspond with the description of chondro-carcinoma of the testis (the only description he had been able to find at that date) given by Ziegler in his "Special Pathological Anatomy," published in 1897. Professor Evans was about to publish a paper on the pathology of this chondro-carcinomatous testis when unhappily he died in March, 1899, of bubonic plague which he contracted when making autopsies on several cases of this disease.

Mr. Foulerton has referred to Dr. Arnold Caddy's report of this case as published in the *Indian Medical Gazette*. Its clinical history, taken with the microscopic picture of the pathological anatomy of the growth, is of great importance. For three and a half years the disease seems to have remained quiescent in the testis, and though 12 years have elapsed since the growth was removed the patient still remains without any obvious sign of recurrence. Such a history would give the false impression that the tumour is benign, but the microscopic appearances clearly prove it to belong to the same malignant group as Case 1, and both cases alike to the same histological class as many other cases which have pursued a rapidly growing and early recurring history.

Both the cases which I have related show that columnar carcinoma of the testicle may remain quiescent, or the patient may be absolutely free of recurrence for many years; but the expectation is always that the disease will ultimately recur, though it may be only after a long time. When, therefore, this fact is taken into account, together with two others—namely, (1) that it is impossible to detect the early secondary infection of the ilio-lumbar lymph-glands; and (2) that the extirpation of these glands, when obviously enlarged subsequent to removal of the testis, is an operation of magnitude and severity, and has been very discouraging hitherto in its results—when, I say, these facts are taken into consideration, we may well be led to hope that the practice of the "radical" or "improved" method of excision of the testis may prove to be successful.

So far, however, in the 17 cases reported of this "improved" operation, there is little, if any, foundation for such hope. In some of the operations the affected glands could not be removed, or, in other words, the "improved" method was found to be impracticable; in other cases in which the glands were successfully removed at the time, the disease soon returned; whilst in the rest insufficient time has elapsed since the operation to permit of any conclusion being drawn as to the ultimate result. Still, hope need not necessarily perish because as yet little, if any, encouragement can be derived from the very limited existing experience. Meanwhile the low malignancy of carcinoma testis, and the long histories of such cases as I have recorded will often afford a prospect to any given patient of prolonged or entire immunity after the testis and cord have been excised by the old method.

THE CAUSATION AND PREVENTION OF CERTAIN TOXIC SYMPTOMS FOLLOWING THE ADMINISTRATION OF SALVARSAN.

BY JAMES McINTOSH, M.D. ABERD.,
GROCERS' RESEARCH SCHOLAR;
PAUL FILDES, M.B., B.C. CANTAB.,
ASSISTANT BACTERIOLOGIST TO THE LONDON HOSPITAL;
AND
H. DEARDEN, M.R.C.S. ENG., L.R.C.P. LOND.
(*From the Bacteriological Laboratory of the London Hospital*, Dr. WILLIAM BULLOCH.)

IT is now generally recognised that intravenous injections of salvarsan are followed in most cases by immediate symptoms of toxicity, these symptoms manifesting themselves as a rise of temperature frequently accompanied by a well-marked rigor and general malaise. Clinically these symptoms have been so constant that we have been led to describe them as "the normal accompanying effect of '606.'" Their onset is between half an hour and one hour after the injection, but it is sometimes even earlier. The temperature rises rapidly and the patient experiences a sensation of cold, shivers, or is attacked by rigors which may last for so long as two hours. The summit of the fever curve usually attains to 102°–103° F., but it has been observed as high as 105°; this point is reached between one and four hours after the injection. Cyanosis is frequently present, and indeed may be very pronounced. Vomiting is common, as also are headaches and pains in the back, the cardio-vascular system, on the other hand, not being markedly disturbed. The acute symptoms are short-lived; about four hours after the injection, accompanied by sweating, the temperature commences to fall. The decline is less rapid than the rise, the

normal limit being reached eight to ten hours after the injection. The patient is now comfortable, and, indeed, the disturbance, however brisk, is so fleeting that ill-effects are seldom complained of on the following day.

It is the causation and prevention of these symptoms that we propose to discuss.

So far as we ourselves were concerned it was quite exceptional to see an intravenous injection pass off without the occurrence of some toxic symptom; indeed, we may say that we had never observed a complete absence of fever when the temperature was taken hourly after the injection. On the other hand, we learned, both verbally and from the literature, that other observers did not experience toxic symptoms so frequently as we did, although undoubtedly they were present in the great majority of cases. This relative freedom from toxicity in the hands of some appeared to be important. It was often held that the rigors were an expression of the toxicity of salvarsan and that they varied in intensity and frequency according to the degree of susceptibility or insusceptibility to arsenic possessed by the particular patient. Clearly, however, it was impossible that one observer should be favoured with patients whose susceptibility to arsenic was minimal, while another should inject only the hypersensitive. The preparation could not be "organotropic" in the hands of one operator and not in the hands of the other. We, therefore, were led to suspect that in these cases it was the operator who was "organotropic" and not the salvarsan; in other words, we began to form the opinion that the occurrence of rigors and the other symptoms of toxicity were due to an error of technique and not to any characteristic of the salvarsan.

From a review of our own experience we arrived at a series of conclusions bearing on these symptoms which appeared to be beyond dispute.[1] We found that (1) the fever was higher and the toxic reaction more marked in secondary and tertiary syphilis than in primary or latent syphilis; (2) the symptoms occurred in non-syphilitic individuals, but not to such a marked extent; (3) the symptoms also occurred after intra-muscular injections, although in this case also to less extent. We were unable to find any common factor in these results except the presence of salvarsan, but for reasons already stated we were not disposed to accept this as the sole cause of the symptoms.

Of the various theories advanced, none could be entirely reconciled to the observed facts, although we were distinctly in favour of the suggestion first brought forward by Schreiber,[2] that the fever in secondary syphilis was the result of the liberation of large quantities of endotoxins from the destroyed spirochætæ.[3] In this view we were supported by the observation that the disappearance of the spirochætæ from chancres was closely connected in time with the height of the fever. This theory might account for the rise of temperature after intra-muscular injections, since this occurred most definitely only in secondary syphilis. The fact, however, that fever occurred after injections in non-syphilitic cases suggested that the injection as such was probably to blame; indeed, Marschalko[4] considered that the percentage of sodium chloride present in the saline solution was a matter of great importance. We have, on the other hand, detected no constant alteration in the toxic symptoms by varying the concentration of sodium chloride. Further, we were unable to accept the suggestion of Wechselmann[5] that the rigors were due to the growth of hæmolytic bacteria in the saline solution. He observed that in one section of his patients rigors were common, while in another they were uncommon. These two sections, males and females, were subjected to different conditions in that the saline used in the case of one section was boiled for a short time and kept ready for use in the incubator, while in the case of the other it was kept on ice. Those patients injected with the incubated saline solution reacted more markedly with toxic symptoms than the others, and further, the symptoms were lessened by a more thorough sterilisation. In our cases, however, there could be no question of a growth of bacteria in the saline solution, since this was always completely sterilised in the autoclave.

In his paper Wechselmann called attention to the work of Bingel,[6] unconnected with salvarsan, upon fever following subcutaneous and intravenous injections of saline solutions. This observer found that fever was elicited in man by subcutaneous and a few intravenous injections of normal saline solution, and that the result was not influenced by alterations in the concentration of sodium chloride. He found, however, that the occurrence of fever was largely diminished by the use of Ringer's solution. These observations appeared to be of the greatest importance, and we at once proceeded to verify them. As a result of our investigations already published[7] we concluded: (1) that every intravenous injection of normal saline solution was followed by symptoms of toxicity more or less severe, these symptoms being indistinguishable from those following the intravenous injection of salvarsan as already described; (2) that these toxic symptoms were very little less frequent after intravenous injections of Ringer's solution than after saline; and (3) that alteration in the concentration of sodium chloride did not affect the result. We therefore inclined to the belief that toxic substances were present in the distilled water used in the manufacture of the saline solution, and this belief was strengthened by previous observations made by one of us upon the toxic effects upon trypanosomes of certain samples of saline solution. It was then found that the toxic bodies could be eliminated from the distilled water by redistillation, and that saline solution prepared from such redistilled water was then innocuous to trypanosomes. Proceeding along these lines we observed that saline solution made from the toxic distilled water, but after redistillation, was entirely innocuous to man, its injection being followed by no symptoms. We had, therefore, eliminated certain toxic bodies from the water by redistillation, and saline solution so prepared after complete sterilisation could be kept indefinitely in a non-toxic condition.

The nature of the toxic substance was not clear; it might be a metallic poison derived from the block-tin still, or it might be a bacterial poison emanating from micro-organisms growing in the distilled water. In order to test whether the water was toxic when first distilled, or whether the toxicity developed later in the laboratory, water was collected direct from the still and immediately made into saline solution and autoclaved. Such water was found to be quite non-toxic, and therefore the occurrence of metallic poisons could be excluded. The experiment also showed, however, that the toxicity was not present at the time of distillation but developed later, and it clearly became necessary to investigate the laboratory distilled water for the presence of micro-organisms. From this investigation we obtained an unlooked-for result, finding no less than 180 millions in 300 c c.—i.e., the usual dose of water administered with "606."

It was not easy to understand how these organisms, after being undoubtedly killed, could give rise to such marked symptoms. They were mostly non-pathogenic cocci and bacilli, and we were not acquainted with any bacterial toxin which could survive a temperature of 115° C. for 20 minutes in the autoclave. However, by means of a filter we removed these organisms from the water in such a way as to allow the passage of any hypothetical toxins, with the result that saline solution prepared in this way was found to be entirely deprived of its toxicity. We therefore concluded that the toxicity of saline solution was entirely due to the dead bodies of micro-organisms which had developed in the distilled water after distillation.*

Having thus demonstrated the toxicity of saline solution and indicated methods by which this toxicity might be eliminated, we applied the principle to the use of salvarsan. The results fully justified our expectations, and the six months following the original publication have been confirmatory. By the use of redistilled water in the manufacture of the saline solution we have eliminated the rigors and toxic effects described above as normally following an intravenous injection of "606," *except in the case of acute secondary syphilis* or in primary syphilis (very large chancres) just before the outbreak of the rash.† In latent or tertiary syphilis or in the later stages of secondary syphilis, as also in parasyphilitic and non-syphilitic individuals, the injection of maximal doses of "606" does not give rise to fever or toxic symptoms except in rare cases.

* Hort and Penfold have recently (THE LANCET, 1912, vol. i., p. 579) questioned whether "salvarsan fever" is due to unbroken bacterial proteins, but allowed that it *may* be due to "degradation products" of such proteins. The difference between our views rests chiefly upon the result of injections of filtrates from bacterial suspensions. These they found toxic, we nontoxic. It is necessary to await the publication of precise technical details.

† In a recent paper Stümpke[8] has sought to show that fever is still invariable after the injection of salvarsan dissolved in re-distilled water, but it must be noticed that all his patients were in the acute stage of the disease.

Since the completion of these observations, which may be examined in more detail in the original publication,[7] we have made further investigations on rabbits in confirmation of the suggested microbic origin of the particular symptoms which we have described. The rabbit is well suited for experiments of this nature, because its temperature is stable and does not vary within narrow limits if due care is taken to keep it in constant surroundings. On the other hand, the heat-regulating mechanism of the guinea-pig is so labile that observations upon its temperature under the conditions of the experiment were quite without value. As a result of many readings the normal temperature of the rabbit taken in the rectum was found to vary between 100° and 101·5° when the animal was kept at room temperature in the autumn.

EXPERIMENT 1. *Showing the influence of sterile normal saline solution injected intravenously into the rabbit.*—The saline solution was made with pure sodium chloride (0·9 per cent.) and ordinary distilled water—sterilisation in the autoclave. The same sample of distilled water stored in a number of flasks was used throughout the experiments. The quantity injected intravenously was 50 c.c., our ordinary salvarsan injection apparatus[9] being used.

Rabbit.	Temp. before injection.	Temp. 2 hours after.
1	100·1° F.	104·2° F.
2	100·2°	103·8°

Next day the temperatures were normal. Injections of ordinary saline solution, therefore, produce fever in rabbits.

EXPERIMENT 2. *Showing the influence of bacterium-free saline solution injected intravenously.*—The technique of this experiment only differed from that of Experiment 1 in the nature of the distilled water used. Instead of this being derived from the supply kept in the laboratory it was collected direct from the still and immediately made into saline solution and sterilised.

Rabbit.	Temp. before injection.	Temp. 2 hours after.	Temp. 4 hours after.
3	100·4° F.	100·4° F.	101 0° F.
4	100·6°	100·6°	100·4°

Injections of microbe-free saline solution thus did not give rise to fever. Both these observations were repeated as follows:—

Rabbit.	Saline solution.	Temp. before injection.	Temp. 2½ hours after.
5	Bacterium free	101·0° F.	101·4° F.
6	,, ,,	100·8°	101·6°
7	Ordinary saline	101·2°	103·2°
8	,, ,,	101·4°	103·0°

EXPERIMENT 3. *Showing the influence on the rabbit's temperature of various bacteria isolated from distilled water when sterilised and injected intravenously.*—We have already mentioned that the distilled water which we used in our observations on man contained 180 million microbes per 300 c.c. Plate cultures were again made from the distilled water and incubated at room temperature. After several days the predominant types were selected and transferred to separate tubes labelled A, B, and C. These organisms were respectively two varieties of Gram-negative cocci and one Gram-negative bacillus. Emulsions of the cultures were then prepared and sterilised in the autoclave at 115° C. for 20 minutes. The emulsions were diluted with bacterium-free saline solution, so that the number of microbes corresponded to the number present in ordinary saline solution (180 million per 300 c.c.). Technique of injection as before.

Rabbit.	Injection.	Temp. before injection.	Temp. 2 hours after.
9	50 c.c. bacterium-free saline + 30 million microbes A	100·2° F.	103·0° F.
10	Do. + 30 million microbes B	100·4°	101·4°
11	Do. + 30 million microbes C	100·1°	102·2°
12	Do. without microbes	99·8°	99·8°

The addition of microbes isolated from distilled water can render a microbe-free saline toxic.

EXPERIMENT 4. *Showing that the dead microbes themselves and not endotoxins are the cause of the fever.*—20 c.c. of the thick emulsions (150 million per c.c.) were passed through small Doulton white filters of 3 c.c. capacity, so that sufficient fluid could be passed through to compensate for any loss of "endotoxins" by adsorption by the filter. 1 c.c. of the filtrate containing the "endotoxins" of 150 million microbes was then diluted with 50 c.c. of bacterium-free saline and injected.

Rabbit.	Injection.	Temp. before injection.	Temp. 2 hours after.
13	50 c.c. of bacterium-free saline solution + 1 c.c. of filtrate B	100·7° F.	100·8° F.
14	Do. + 1 c.c. of filtrate C	101·0°	101·0°
15	Do. + 1 c.c. of emulsion B unfiltered	100·3°	104 2°

Thus the fever is produced by the bacterium and not by any hypothetical endotoxin.

EXPERIMENT 5. *Is a second injection of saline solution followed by increased toxic effects?*—The question of increased toxic effect after repeated injections of saline solution and in particular after salvarsan injections is of great practical importance. In the literature several instances have been recorded in which severe symptoms followed a second injection of salvarsan, although the first injection followed a normal course. Two factors might be involved in this phenomenon—the salvarsan (which will be referred to later) and the bacterial contents of the saline. If the latter were the cause of increased toxicity after the second injection, it would be expected that such symptoms would be of an anaphylactic nature. We have, however, been unable to demonstrate any increased toxic effects by the repeated injection into rabbits of the number of micro-organisms present in ordinary saline solution. Rabbits 1 and 2 were reinjected with 50 c.c. of ordinary saline solution 12 days after the first injection (*vide* Experiment 1, *supra*).

Rabbit.	Temp. before.	Temp. 2 hours after.
1	100·4° F.	103·8° F.
2	100·0°	104·0°

Rabbits were then injected with 50 c.c. of ordinary saline solution, and 17 days later with 150 million microbes A, B, and C (*vide supra*) diluted with re-distilled water saline solution to 50 c.c.

Rabbit.	Temp. after first injection.	Second injection.	Temp. after second injection.
16	103·2° F.	Microbes A	102·2° F.
17	102·4°	,, B	104 2°
18	103·6°	,, C	104·5°
19	104·0°	Re-distilled saline alone	101·2°

No anaphylactic symptoms were observed.

To recapitulate these experiments on rabbits:—

1. The injection of sterile laboratory saline solution is toxic.
2. The injection of microbe-free saline solution is non-toxic.
3. The addition of dead bacteria isolated from the laboratory saline solution before sterilisation to the non-toxic microbe-free saline solution renders the latter toxic.
4. The toxic effect is due to the microbes themselves and not to endotoxins derived from them.
5. The toxic effect is not due to any one variety of microbe.
6. No increased toxicity or anaphylaxis was found to follow a second injection of the microbes.

As a result of the researches which have been carried out under Professor Ehrlich's guidance upon the relation of water bacteria to fever after salvarsan injections, the following explanation has been suggested. Yakimoff and Yakimoff[9] have shown that salvarsan injected into animals along with various dead bacteria is more toxic than salvarsan alone; that is to say, when such bacteria are present, a smaller dose of salvarsan will suffice to kill the animal than when no bacteria are present. It is considered that this increase in toxicity is the cause of the rigors and toxic symptoms which are observed. The salvarsan is more organotropic in the presence of bacterial toxins and less parasitotropic, and it thus follows that salvarsan given in toxic saline solution is a less efficient spirochæticidal remedy than salvarsan dissolved in non-toxic saline solution. As regards the increased toxic symptoms usually noticed in secondary syphilis, the same argument will apply. It is invariably found that a dose of a chemotherapeutic substance which will be readily borne by a normal animal will kill a similar animal infected with trypanosomes or spirochætæ; in other words, the substance is relatively more toxic in an infected animal than in an uninfected. Yakimoff and Yakimoff have definitely shown that the toxicity of salvarsan tested upon rabbits infected with trypanosomes is proportionate to the number of trypanosomes present in the rabbits. Similarly the toxicity of salvarsan in syphilis is at its maximum when the number of spirochætæ is at the maximum—i.e., in secondary syphilis. Increased reactions may therefore be expected in such cases.

As a result of our investigations we are of opinion that this theory does not explain adequately the phenomena observed by us. We have demonstrated that all the typical symptoms of a salvarsan injection may be produced by the injection of the actual saline solution without the addition of salvarsan, and that the occurrence of these symptoms after salvarsan injections may be prevented by suitable treatment of the saline solution. Thus salvarsan cannot have any effect primarily or secondarily upon the rigors. These occur as a result of the bacterial contamination of the water with or without the presence of salvarsan. In our view the toxicity of this substance is not increased by the addition of bacterial toxins. In a "normal" individual the toxicity of salvarsan is practically *nil*, whether bacterial toxins are present or not. This view may be tabulated as follows:—

Toxicity of saline solution	= 0
,, saline solution + water microbes	= 1000
,, saline solution + salvarsan	= 10 (normally)
,, saline solution + microbes + salvarsan	= 1010

The precise mechanism by which the dead bacteria exert this toxic effect is doubtful, but from the similarity between the symptoms it may be supposed that the bacteria exert an

action upon the body similar to that produced by the intravenous injection of various foreign proteid substances as described by Vaughan, Cumming, and Wright.[10] The experiments of Yakimoff and Yakimoff might indeed explain the phenomenon of fever occurring in secondary syphilis after the exhibition of salvarsan dissolved in microbe-free saline solution. The toxicity of the salvarsan might be increased by the larger number of spirochætæ in the sense that a smaller dose may kill a secondary syphilitic than would be necessary in the case of a latent syphlitic. On the other hand, it might be objected that the rigors and transient toxic symptoms observed are not in any way suggestive of arsenical poisoning. The type of temperature curve suggests that the phenomenon is an artificial crisis such as is produced in relapsing fever by the administration of salvarsan, and the rise of temperature in this case would be due to the liberation of endotoxins from the dead spirochætæ. To this view we still adhere. The rigors and toxic symptoms which occur in secondary syphilis must be different in origin from those occurring in other forms of syphilis, because they continue in spite of the use of microbe-free saline solution. They seldom occur later than the first week or two after the outbreak of the rash, no doubt owing to the fact that, after the first invasion of the system, the great majority of the spirochætæ are rapidly destroyed by natural processes. Further, there are slight clinical differences between the "saline" rigors and those occurring in secondary syphilis after the use of salvarsan dissolved in microbe-free saline solution. The latter occur rather later after the injection, the temperature seldom starting to rise for three or four hours. This is in support of the endotoxin view, since we have found that there is no disappearance of spirochætæ from chancres for four or five hours after an injection. There is a latent period first and then the destruction of the spirochætæ is found to run parallel with the height of the fever, so that, by the time the normal limit is again attained, no spirochætæ can be detected.

Thus we conclude that the phenomena of rigors in syphilis treated by salvarsan dissolved in toxic saline solution and rigors occurring in secondary syphilis after the use of non-toxic saline solution are due to two entirely different factors. In the first case they are due to the dead bacteria in the water acting as a foreign proteid, while in the second they are due to bodies liberated from the spirochætæ after their destruction.

The elimination of the more excessive toxic symptoms by the use of bacterium-free saline solution is a matter of some value; so much so that Professor Ehrlich urges that everyone who makes use of these injections should distil his own water. This is undoubtedly desirable. Commercial distilled water, as shown by P. Th. Müller,[11] is often grossly contaminated with bacteria, and the difficulties in the preparation of a *certainly* pure saline solution are sufficiently great to render the transfer of the responsibility of manufacture unsatisfactory. It will be clear that in the absence of toxic symptoms due to the water the slight toxicity due to the salvarsan as such will be more easily borne, and larger doses may therefore be used. For the last six months we have never given an adult less than the maximum (0·6 grm.) at one time. Again, the relative contra-indications to the use of salvarsan lose much of their importance. The cardio-vascular system is not now put to the test in any way so severely as formerly, neither is a diseased nervous system so prone to develop stormy local "reactions." The exacerbations of lightning pains, headaches, and similar symptoms in such patients have been thought to represent a "local reaction" due to the effect of "606" upon the spirochætæ; since using bacterium-free saline solution, however, we have not observed these occurrences. We therefore consider that the chances and risks attending the treatment of tabetics and general paralytics, if such treatment is considered to have sufficient value, may be appraised less highly than was formerly the case.

It must not, however, be supposed that with satisfactory saline solution salvarsan becomes an entirely indifferent substance in every case; on the contrary, it is now more possible to recognise its own measure of toxicity. Formerly it was the general rule for the toxic symptoms to be less marked after second or third injections. Now we are of opinion that such toxic symptoms as may be met with may become progressively more marked after repetition of the dose at short intervals. This, without doubt, is not the result of any process which may be described as "anaphylaxis," but simply represents the accumulative effect of large doses of arsenic. The symptoms which we have met with are usually most marked in the gastro-intestinal system, and it is interesting to note that the recent work of Kochmann[12] has shown hæmorrhagic gastritis and enteritis to be the prevailing lesion in animals after fatal doses of "606." These toxic symptoms are by no means invariable, and extremely rare after first injections. The relative harmlessness of the drug, however, has not led us to relax any of the precautions which we have formerly adopted. We never administer "ambulatory treatment."

The practical application of these principles is not devoid of difficulty. In order to ensure as far as possible an absence of toxicity, the preparation of the water must be conducted with the greatest possible care. All vessels must be absolutely clean. The water must be collected direct from the still, and immediately made into saline solution, and *sterilised* in the most complete bacteriological sense. When once a flask has been opened the contents must be used at once, remnants cannot be preserved in the ice chest for future use.

In conclusion, we wish to touch briefly upon another aspect of the toxic saline solution.

It is of general interest to record the cases of death which have followed the administration of salvarsan; from such records luminous conclusions may be, and have been, drawn. THE LANCET itself has recently referred to several of these cases in its "annotations." From many of the reports, we think, a reasonable person could hardly avoid gathering the impression that salvarsan is a dangerous substance and that fatal results have frequently followed its administration. Incidentally the suggestion is often present that such fatal results are hushed up by salvarsan enthusiasts in order that the public may not recoil from the risks of treatment. These suggestions emanate from mercury or hektin enthusiasts. Anyone reviewing the incidents which have surrounded salvarsan since its introduction might reasonably turn from their contemplation with feelings of disgust. Thus we read in the *Times* under the heading "Preparation 606" the following:—

> Paris, Feb. 7.—Professor Gaucher has reported to the Academy of Medicine that numerous deaths have occurred in France, Germany, Persia, and Rumania through the employment of the remedy known as "606," the patients dying in a state of coma after a few injections. Professor Gaucher also complains of attempts to hush up such fatalities in France, and insists that the remedy is deadly and of small therapeutic efficiency.

We assert that the impression left by this statement upon the great majority of persons will be false.

Turning to the other side of the question, we find that writers of greater judgment have advised caution in the use of salvarsan or have even presented a volume of objection to it. Such papers have been published in THE LANCET. It appears to us, however, that many of these objections are open to criticism in that they presume that a death obviously following an intravenous injection of salvarsan is necessarily *due* to this chemical substance. It is quite clear that when one refers to an "injection of salvarsan" one makes use of a loose expression. The injection consists of water, sodium chloride, sodium hydrate, and usually micro-organisms in addition to salvarsan. As a result of our observations we have come to the legitimate conclusion that these micro-organisms being the cause of the severe reactions which are sometimes met with are also the cause of a number of deaths which have been recorded. Such deaths are, therefore, preventable and not due to salvarsan. We do not think that the microbes are the cause of all deaths following salvarsan; there are, no doubt, other factors; we, however, assert without fear of contradiction that the number of deaths and the degree of toxic results will vary largely with the skill of the operator or the facilities open to him. We look upon it as ridiculous to compare the facilities of Persia at the present day with those of Europe, and equally ridiculous to quote results alleged to have been obtained in that country as evidence either against or for the use of salvarsan elsewhere.

THE OPERATIVE TREATMENT OF GRAVES'S DISEASE.[1]

BY WILFRED TROTTER, M.S. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON, UNIVERSITY COLLEGE HOSPITAL, ETC.

MY contribution to this discussion is made with a good deal of diffidence and hesitation, because my experience of the operative treatment of Graves's disease is quite a small one, and I regard many of the most interesting problems of the subject as being so far from solution as not profitably to be entered upon here. Limited as one's experience is, and it is based on less than 50 cases, it has enabled one to come to certain rough practical conclusions which I will attempt briefly to put before you.

In comparing the medical and surgical treatments of Graves's disease it must be kept clearly in mind that the former does not attempt to influence directly the course of the disease, but is limited to putting the patient under favourable conditions while the disease runs its natural course, to end in arrest, spontaneous cure, or death. Operative treatment, on the other hand, is intended to be specific and to deal directly with the disease itself. It is clear, therefore, that we have to take into account not merely the comparative mortalities of the two methods, but also the length of the natural course of the disease and the condition of the patient during its progress. That the condition of a patient with severe Graves's disease is a very miserable one is common knowledge and is strikingly shown by the willingness of the patients to submit to operation, although they are rendered morbidly nervous by the disease and have usually been told before they come to the surgeon that the operation is an excessively dangerous one.

While I do not attempt to minimise the fact that the mortality of the operation is a considerable one, and possibly greater than that of the untreated disease, I am convinced that it would be justifiable to run a good deal of risk if it were the means of avoiding the years of miserable illness which are the lot of so many of the patients. It seems to me, therefore, that now we know the operation can be done without, at any rate, a very great mortality, the principal interest centres round the results rather than around the actual death-rate. I confess that to me discussions as to the relative death-rates of the untreated disease and of the operation—now we know that they are not widely different—seem to be comparatively useless, whereas the question of what relief can be obtained by operation is of the utmost importance. Unfortunately it is a most difficult question to solve in a way satisfactory to any fairly sceptical inquirer.

There is no disease more difficult to deal with statistically than exophthalmic goitre. Not only does the fully developed disease include certain well-defined types, but this central group is surrounded by very numerous forms which constitute an unbroken series, from unmistakable Graves's disease on the one hand to wholly non-toxic goitres on the other. It is the actual difficulty in drawing sharp lines of distinction which makes one look upon all statistics of the disease, surgical or medical, with a certain caution. The same ambiguity renders the statement of results equally difficult to interpret. Anyone who has some experience of the operative treatment knows that all grades of relief are met with, from total and permanent disappearance of all symptoms to the mere temporary subsidence which follows all operations. To divide the results into classes according to cure, much improvement, no improvement seems to me to put much too great a strain upon the judgment of the observer, and can only be of any considerable value when the material dealt with is of enormous size.

Again, the selection of a single objective sign such as pulse-rate, exophthalmos, or body weight as a measure of improvement is open to equally serious objections. Exophthalmos or tachycardia may, as is well known, become stereotyped and persist as an isolated phenomenon while the patient is perfectly well in every other respect. The body weight is at first sight a more valuable standard. Experience has shown me—though I do not believe the fact is generally recognised—that the body weight may show abnormal variation in *both* directions in Graves's disease—a pathological diminution being succeeded by a pathological increase, or *vice versâ*.

I may mention two cases which illustrate how fallacious a mere record of weight may be. In each of them the first sign of disease the patient noticed was that she became very fat. As the disease developed severe emaciation came on, and at the time of the operation both patients were extremely wasted, the weight of one, for example, having fallen from the abnormal figure of 11 st. to below 6 st. In each case after the operation the patient rapidly put on flesh, and there was great improvement in all the symptoms. Then a stage was reached when the patient was uncomfortably fat, and though much better than before yet had a distinct residuum of symptoms. A second operation was now done. Following it all the symptoms completely disappeared and the patient actually lost weight, the one in whose case I have given the figures losing over a stone and settling down to 10 st., her normal weight.

In view of these and similar facts it would, in my opinion, be useless for me to attempt to set the results of my small experience before you in tabular form, and I shall therefore merely try to give as frankly as I can such practical general conclusions as I have come to.

In the first place I propose to deal shortly with the question of mortality. The operation is one which shows a marked contrast with all other operations on the thyroid. Of these latter, as is well known, there is practically no death-rate. In a considerable experience of thyroid operations, excluding exophthalmic goitre but including a fair proportion of malignant and of intrathoracic goitres, I have never lost a case from the operation, and that, of course, is the common experience. Graves's disease, on the other hand, shows a mortality which was in the early days heavy and is even now considerable. The mortality, however, presents this encouraging peculiarity, that it can be, and invariably is, reduced as the surgeon acquires experience in the special requirements of the operation.

Taking the experience of representative surgeons on the continent, you will find that out of the first 50 cases of any given surgeon he will usually lose 5 as a direct result of the operation. This 10 per cent. mortality is usually considerably reduced in a surgeon's later work, and is no doubt to some extent to be regarded as a measure of the difficulty in acquiring the special kind of knowledge which goes to successful operating on these cases. I should be inclined to venture the opinion that a reduction to 5 per cent. should be generally possible, and I think that if that could be established as a standard figure the operation could be regarded as having made out at any rate a strong *primâ facie* case for being tried on a large scale.

In my own cases I have had a mortality of 10 per cent. This is undoubtedly, as I have already said, a high figure, and I may add by way of comment that it is based on a strict definition of the disease and an unwillingness to admit the larval forms except on very good evidence. Moreover, I have never felt justified in refusing to operate on a patient on account of the severity of the symptoms, for it is just the worst cases which are most urgently in need of relief, and for which if the operation is survived the most brilliant results can be attained.

Turning now to the results, one may begin with the general statement that all patients who get over the operation show some more or less permanent improvement, while in some all symptoms disappear as if by magic within a few days.

The two most definite statements one can make are, first, that patients with a small firm thyroid and marked symptoms scarcely ever show more than a temporary improvement. In them the operation is never seriously dangerous and never really satisfactory. The class is not a large one; I have dealt with not more than three or four definite cases.

Secondly, early mild cases—that is, cases without an abrupt onset, and showing a well-marked interval between the appearance of the physical signs and the development of the symptoms—invariably do well and are cured by a single operation. This class is well-defined, easy to identify, and allows of a positive prognosis being made. They constitute

[1] A paper read on Feb. 27th at a joint meeting of the Medical, Surgical, and Anæsthetics Sections of the Royal Society of Medicine.

about a quarter of my material. The operation seems entirely free of danger, and no such case has ever given me any anxiety.

The bulk of the cases—more than half my material—presented the disease in a severe form, the symptoms being marked as well as the physical signs and the goitre well developed. In such cases the improvement seems to vary with the amount of thyroid removed, and in about half of them is permanent and more or less complete. A second operation may be necessary because of a residuum of symptoms being left or because a recurrence takes place. I am inclined to say of this class that at least half can be permanently cured, though some need a second operation to secure this result. Of the rest, the disease can be greatly relieved or brought to a standstill in most.

Anything more detailed than this rough analysis would not, in my estimation, at the present time be of much value, but I should like to add that I am deliberately giving cautious and conservative estimates of the results.

To turn for a moment to the more technical aspects of the subject I should like to add a few words as to anæsthesia and technique of operating. I have used chloroform, open ether, ether by intravenous infusion, and local analgesia.

There seems to be a strong current of feeling at the present day against the use of chloroform in these cases, and I must admit that I have been influenced by it. There can be no doubt that the drug is more toxic than ether, and I feel that we are not justified in adding any risk, however small, to those necessarily contingent upon the operation. Still, I should like to say that in all my earlier cases chloroform was used and gave satisfactory results in some of the severest. The pulse-rate practically always diminished during the anæsthesia. Of course, such an anæsthetic should never be given except by the most accomplished expert, and I was fortunate in having for the most part the assistance of my friend Dr. Herbert Scharlieb. Ether by infusion I do not regard as presenting any considerable advantage except possibly in the elderly where pneumonia is to be feared.

At present I rely entirely upon ether by the open method in combination with atropine, morphia, and scopolamine, and in certain cases upon local analgesia. In connexion with the use of ether I should like to lay stress upon the importance of the preliminary atropine and upon the anæsthetist satisfying himself that this drug is acting before he begins the anæsthetic.

With regard to the actual operation, the choice of the time for its being done is in my opinion very important. I do not, however, acquiesce in the view that has been expressed that the patient should be submitted to several months' medical treatment as a preliminary. After all, this merely means watching the course of the disease for such a period, and I think that after some experience one can estimate the type of the disease and the course it is likely to follow without an expenditure of time so discouraging to the patient. As to the existence of an acute exacerbation, I should not hesitate to operate at such a time if I thought the patient's life was being endangered by the condition, though as a general rule it would be better to wait. Bronchitis, tonsillitis, and acutely inflamed cervical glands which are common complications I regard as absolutely contra-indicating operation for the time.

I have come to regard the mental state of the patient as perhaps the most important feature of the case in prognosis both as to the danger of operation and as to the final result. All the patients are nervous—that is, of course, part of the disease; but not all are frightened, and the really frightened patient is the most dangerous of all. To explain this, I do not think it necessary to invoke the changes in the cerebral cells of frightened animals described by Crile. A much simpler explanation seems to me available. Fear acts by precipitating an access of tachycardia during which the pulse-rate is perhaps uncountable for hours. In such circumstances the anæsthetic does not produce the usual steadying of the pulse, and the shock of the operation or the least amount of cyanosis from laryngeal spasm may be fatal. It is in these cases that the modern method of ether administration is so valuable. In hospital nowadays in my cases the patient is always anæsthetised in bed in the ward.

In the actual operation itself speed is no doubt valuable, but it is much less important than gentleness of manipulation which is absolutely indispensable. A large incision is essential to give easy access to the gland, and any kind of pulling is to be strictly avoided. In getting out the upper pole traction is very easily transmitted to the superior laryngeal nerve with the immediate result of causing laryngeal spasm and cyanosis—a most dangerous complication. Drainage is sometimes necessary when the anæsthetic is ether, to allow of the escape of blood. Otherwise I never use it, and I have not seen the slightest evidence that the thyroid secretion can cause symptoms by being absorbed from the wound.

The operation done in my cases has always been a partial thyroidectomy, usually the removal of one lobe and the isthmus.

The chief causes of death are shock during or immediately after the operation, an exacerbation of the disease within the next 24 hours, or pneumonia in the first week. I have lost two cases from shock, one from an acute exacerbation and one from pneumonia, and I am convinced by the study of that experience that the danger of the occurrence of such complications can be greatly reduced. This is to be effected by adequate mental and physical preparation of the patient, the choice of the best time for operating, the right anæsthetic for the given case, and the most careful avoidance of any traction upon or crushing of the gland. Such conclusions have been entirely borne out by my later experience.

Harley-street, W.

"ACHING THROAT." [1]

BY W. H. KELSON, M.D., B.S. LOND., F.R.C.S. ENG., D.P.H. CAMB.,

SURGEON AND PATHOLOGIST TO THE LONDON THROAT HOSPITAL.

IT is known to us all that there are certain affections of everyday occurrence which, while not having the immediate destructive effect upon life which appertains to the various forms of malignant disease, yet in a way have considerable importance, since by their persistent character and worrying nature they, as it were, gnaw their way into the comfort and happiness of their unlucky victims, constantly obtruding themselves on their consciousness and interfering with their pleasures like spectres at a feast. To one of these I have given the name of "aching throat," and I have decided to submit to your notice and consideration a few facts concerning it, because, although from childhood upwards we are all familiar with "sore-throat," yet aching throat, although more troublesome because more permanent, has not, I think, for some reason received the amount of attention it deserves.

The patients who come complaining of this trouble have generally arrived at, or are approaching, middle life, and the aching may vary very considerably in degree and somewhat in character. On examination they may be found to have the signs of chronic pharyngitis, with swelling, congestion, and catarrh, hypertrophy of the pharyngeal bands and granular patches, associated with coughing, hawking, and other efforts, varied and anomalous, some voluntary, others reflex, to clear the throat. Also there may be associated with it enlargement of the post-nasal, faucial, and lingual tonsils, the first least, the last most commonly, or nasal obstruction and discharge, also enlarged veins, bad teeth, and enlarged glands. All of these I have observed, but not one of them is pathognomonic, for in some of the worst cases one comes across they are absent. It is a somewhat curious fact, at least as far as my experience goes, that those cases of pharyngitis with swollen deeply congested pharynx, soft palate and uvula, with great irritability and excess of mucus, such as one sees often in persons indulging in excess of alcohol and tobacco, are but seldom troubled with aching throat, though dryness may be a marked symptom, and, on the other hand—indeed, in some of the worst cases—I have seen the pharynx when examined show very little or no evidence of disease at all.

As regards general condition, these patients are sometimes anæmic or their history or other parts of the body point to gouty or rheumatic tendencies; much more commonly, however, the patient suffers from dyspepsia of the flatulent variety which may have to be carefully inquired into, for if simply asked whether or no he suffers from indigestion the patient generally replies in the negative, as he has neither abdominal pain nor vomiting, but is distended with wind,

[1] A paper read before the Medical Society of London on Feb. 12th, 1912.

the belching up of which gives him considerable relief. In taking the history of these patients it is necessary to carefully analyse their feelings, or one of the cardinal signs may not be elicited—viz., that the aching, instead of being increased by swallowing food, as is the case in sore throat, is diminished thereby, as though the bolus in some way soothed and comforted the parts; swallowing liquids, however, may increase the aching.

In trying to throw some light on this symptom of aching throat, it will be well to first shortly consider two points—viz., the nerve supply to the naso-pharynx, pharynx, and upper part of œsophagus, and the vagueness of the sense of locality in this region.

Briefly taking the nerve supply first:—From above downwards, we find the posterior and external branches of the spheno-palatine ganglion of the superior maxillary together with the pharyngeal nerve and Vidian; the inferior maxillary by its various branches sensory and motor, the facial to certain muscles used in swallowing, the glossopharyngeal by numerous branches both muscular and to the mucous membrane, the pneumogastric, together with the spinal accessory, pharyngeal and laryngeal branches to mucous membrane and muscles of the throat, also to the external auditory meatus and œsophagus; the hypoglossal to the muscles of the pharynx, also the upper cervical spinal nerves and the sympathetic.

As regards sense of locality, one notes in the naso-pharynx and pharynx a vagueness which may be misleading. For instance, when one passes the Eustachian catheter through the nose in the ordinary way for deafness, and the point impinges on the orifice of the Eustachian tube above the palate, the patient is apt to point to a spot below the angle of the jaw and say that he feels it sticking in there. Again, this vagueness is well illustrated by the common incident of one's having to search for a bone sticking in the throat when the foreign body is generally found in quite a different part from that to which the patient had drawn our attention.

Also, how often we find pain due to disease of the throat referred to the ear. And patients suffering from malignant disease of the lower end of the œsophagus sometimes refer their discomfort to the cervical region, and I myself have had a case in which the chief symptoms were aching and unpleasant sensations referred to the throat and wasting. In this woman examination of the pharynx and œsophagus by the direct method showed nothing abnormal, but the patient died with disease of the liver.

I think, therefore, we may say without fear of contradiction that we have in this region not only an exceedingly rich and varied nerve-supply, but also find here a marked tendency to refer sensations to other areas than those actually stimulated.

One would like first to mention here that one knows very well that there are those who are inclined to somewhat pooh-pooh these cases and dismiss them under the general term "neurotic," and consider the aching allied to the constricted feelings of the throat and the lump rising or globus hystericus of true hysteria, but I cannot admit this explanation as satisfactory, for although aching throat may, of course, occur in a neurotic subject, and this explanation is apt to cross our minds if we find nothing locally, yet in the great majority of cases further examination fails to reveal other signs of hysteria.

Again, I would disassociate from the subject under discussion the aching pain felt by those who use their voices largely, such as teachers, clergymen, lecturers, public speakers, singers, and the like, and in whom it is associated with more or less hoarseness, as this seems allied to the so-called muscular aching from which many persons suffer after the immoderate use of any muscle in the body, leaving aside the question as to whether the pain be actually in the muscle itself or not; for aching throat occurs commonly in those who are not large voice users at all. On the other hand, they often complain that the aching is much worse when they get tired, using the term in the general sense. Here are some short notes of illustrative cases, private and hospital.

CASE 1.—The patient, a domestic servant, aged 34, attended hospital complaining of aching throat. She had six months previously suffered from tonsillitis, but volunteered the statement that this was quite a different pain from that which she had then, and noticed that taking food, instead of aggravating it as it did before, now gave temporary relief. On examination the throat looked anæmic, but beyond a slight enlargement of the faucial tonsils nothing else abnormal could be detected. Bowels very constipated. After advice as to diet and regulation of the bowels marked improvement took place, and patient ceased to attend.

CASE 2.—A healthy looking man, aged 40, came complaining of discomfort in the throat which he described as being of an aching and burning character. Asked as to its position he located the site of maximum intensity as being about the situation of the thyroid cartilage, but sometimes extending up to the ear and down to the sternum. On examination it was noted that the teeth were very much decayed and some granular patches present on the pharyngeal wall. Post-nasal space normal. Subsequently an examination by the direct method was made, but no abnormal appearances could be detected in the lower part of the pharynx or œsophagus. He suffered largely from flatulence, and belching gave some relief to the pain. No pain or difficulty in swallowing solid food, which gave immediate temporary relief. Liquids, however, he stated seemed to increase his discomfort. Advised to seek the assistance of a dentist and ordered a mixture containing rhubarb and soda. Reported later that he had been better for a time, but that the pain had returned. The granulations on the pharyngeal wall were now cauterised with the galvano-cautery, and when last seen he was free from the aching.

The next case does not, strictly speaking, belong to this category, but is introduced because of the side light it throws on the subject.

CASE 3.—A man, aged 45, came complaining of pain in the throat, sometimes of an aching, sometimes shooting in character, the seat of maximum intensity being in the region of the lesser cornu of the hyoid bone on the left side. No pain on swallowing, no symptoms of indigestion, no flatulence. Patient had previously tried numerous remedies and had the galvano-cautery applied to the pharynx, but the aching, though intermittent, never disappeared. On making a careful examination of the floor of the mouth I found a small salivary calculus in Wharton's duct, after the removal of which the pain permanently disappeared.

Since this occurrence I have made a point of examining carefully the floor of the mouth in all cases of aching throat, but in only one other case—viz., that of a lady about 50 years of age—have I ever succeeded in detecting anything in the shape of a salivary calculus.

CASE 4.—A man, 52 years of age, who had been abroad a good deal and had had malaria, complained of aching and throbbing feelings in the throat, and referred to the back of the palate as the seat of its maximum intensity, but he was somewhat vague on this point. He admitted that he suffered from indigestion and flatulence. On examination of the mouth and pharynx nothing abnormal was detected, nor did posterior rhinoscopy reveal any abnormality, though the airway through the nose was much interfered with by a deviated septum. The bowels were regulated and the indigestion treated with partial relief. Later on the nasal stenosis was relieved by a submucous resection operation, after which he expressed himself as feeling all right and ceased to attend.

CASE 5.—A housewife, aged 52, came complaining of trouble, some aching in the throat. She was very much worried by the pain, which she feared was due to cancer, from which her mother died. She swallowed food very slowly, and believed that certain articles of food made the pain worse afterwards, but she had no real difficulty in getting a bolus down. She got much flatulent distension and belching after food. Lingual tonsil enlarged but no other abnormality detected, nor did the direct examination of the œsophagus by means of Brüning's apparatus give evidence of anything pathological. Aperients and regulation of the diet produced improvement, but the case has shown marked relapsing tendencies.

Treatment.—I have already spoken of the local pathological conditions which I have found at different times associated with aching throat, but except, of course, in such a case as calculus I would strongly advise the avoidance of radical treatment in reference to these in the first instance; I think it better to be content with the ordinary cleansing nose washes, sprays and gargles containing chloride of sodium, biborate of sodium, and the bicarbonate, boric acid, potassium chlorate, and the like, for operation may prove disappointing in results both to surgeon and patient, and should therefore not be lightly undertaken nor advised since we cannot promise that removal of, say, a much enlarged lingual tonsil will cure aching throat, any more than the removal of polypi and other morbid conditions in the nose can be guaranteed to cure asthma.

At the same time one must give proper attention to general pathological conditions such as anæmia, though I must admit that the administration of arsenic and iron after due regulation of the bowels has not given the results hoped for as regards the throat discomfort, but has, in fact, been decidedly disappointing. I must say the same though in a less degree as regards medicines which have been found to give relief in gouty conditions—e.g., colchicum, piperazine, and salts of lithium and potassium, such as the citrate and bicarbonate.

As regards rheumatism, the fact that the pain closely resembles that which occurs in muscular rheumatism, and also since it has been repeatedly shown not only that acute pharyngitis and tonsillitis are often markedly benefited by anti-rheumatic remedies such as salicylate of soda and aspirin, but also that these diseases are often the immediate forerunners of acute rheumatism, one would be led to reasonably expect that these remedies would give relief in aching throat, but they have failed to do so in my hands.

On the other hand, a very large proportion of patients do

suffer, and have suffered, from chronic dyspepsia, and the appetite is commonly deficient, though occasionally it is the opposite. Although actual abdominal pain and vomiting are not common, retching frequently occurs with feelings of oppression and depression after food and eructations and distension with gas. The tongue may present morbid appearances, and a disagreeable taste is often present. Constipation is very common, diarrhœa rare.

What the exact relationship of aching throat is to this condition it is difficult to say, but that it is a very close one I am quite certain, and the best results are to be obtained by suitable treatment to the digestive organs, supplemented in some cases by operative treatment on the throat and nose.

In order to relieve the dyspepsia, first of all the teeth must be examined, and the patient referred to a good dentist if necessary. The diet must be inquired into and corrected. As regards the vexed question of alcohol, it certainly seems in some cases to bring on and in others to aggravate the aching, and I think, on the whole, these patients are better without it. I know of several cases in which washing out the stomach has completely relieved the aching, and consider it a most valuable form of treatment if not carried to excess.

Amongst the drugs which have proved most useful, gentian, calumba, strychnine, bicarbonate of soda, bismuth, magnesia, and charcoal are the principal. Constipation is very common and very troublesome, and if not relieved by careful dieting I have found the best drugs to use to be cascara, podophyllum, and sulphur; also small doses of mercury followed by a saline aperient are valuable. As a means of giving temporary relief massage is useful, and so is the galvanic current, but as permanent curative agents both are disappointing.

Smoking, if in excess, of course must be forbidden, but I have not been able to convince myself that moderate smoking was in itself a cause of aching throat, and certainly many women suffer from it who do not smoke at all, and one finds a good many patients who are anxious to get well and willingly abstain entirely from both tobacco and alcohol, and yet the pain continues.

In conclusion, to summarise matters a little we may say that experience has shown that aching throat is more commonly associated with flatulent dyspepsia than anything else, and this seems to act either by the formation of toxins, or possibly the aching may be a referred pain, such as that which occurs in the ear so commonly in disease of the larynx and upper part of the œsophagus. There may also, however, be local conditions which, if they do not actually cause, certainly accentuate aching throat; these must be sought out and dealt with in obstinate cases, not forgetting that the condition of the nose and accessory sinuses has a very distinct bearing on the state of the pharynx, as also have the teeth.

I will finish with one word of warning—viz., only after very careful examination must we arrive at our conclusions as to the cause of aching throat. To overlook malignant disease is disastrous.

Cavendish-place, W.

CENTRAL MIDWIVES BOARD.—A meeting of the Central Midwives Board was held on Feb. 22nd, at Caxton House, Westminster, with Sir Francis H. Champneys in the chair. Letters were considered from the superintendent of the Rescue and Maternity Homes, Moss Side, Manchester, and from Dr. C. W. Brown, of Manchester, asking that candidates whose certificates of attendance on cases and attendance during the lying-in period are not signed in accordance with the existing Rules may nevertheless be admitted to the next examination. The Board decided that the superintendent of the Rescue and Maternity Homes and Dr. Brown be informed that the candidates cannot be admitted to the examination, their schedules not having been signed in accordance with the Rules. Letters were considered from Dr. W. J. Howarth, county medical officer of Kent, reporting the suspension of two midwives for a period in excess of 24 hours, with the special circumstances in connexion with the cases. The Board directed that Dr. Howarth be thanked for his communications, and that he be informed that the action taken is approved by the Board. A letter was considered from a certified midwife inquiring as to the antiseptics to be used for cleansing the infant's eyelids as prescribed in Rule E, 2 (b). The Board decided that the reply be that the Board has designedly refrained from prescribing the use of specific antiseptics.

FURTHER EXPERIMENTS ON THE TREATMENT OF INOCULATED RAT SARCOMA AND OBSERVATIONS ON CERTAIN ACCOMPANYING BLOOD CHANGES.[1]

BY HELEN G. GRÜNBAUM, M.D. BIRM.,
AND
ALBERT S. GRÜNBAUM, M.D. CANTAB.
(*From the Department of Pathology of the University of Leeds.*)

IN a previous communication[2] we published the results of some experiments on the treatment of malignant disease in rats and mice, showing that by the injection of antivenom (horse) serum it was possible to effect regression of inoculated tumours in rats provided they did not exceed 1·5 cm. in diameter. We have found since that by the simultaneous administration of adrenalin with the antivenom serum (Pasteur Institute) yet larger growths can be made to disappear in these animals.

In this second series of 77 tumours there have been many which reached or exceeded 2 × 1 cm. in size. An idea of the relative size of such a tumour may be gained from the fact that the average weight of the animals used has been 40 grammes, and of the tumours 8 grammes—that is, a tumour equal to one-fifth of the body-weight may be cured.

Of these 77 tumours, 34 of the largest at the time of starting the experiment have been treated, while 43 were kept as controls. Of the 34 treated, 24 were cured, 3 became larger, while in 7 the animals died before the conclusion of the experiment. Of the 43 control tumours, only 8 regressed, the remaining 35 increased in size, while 12 animals died before the conclusion of the experiment. In other words, while 70 per cent. of the treated tumours regressed, only 18·6 per cent. of the untreated tumours did so, although the original selection of small tumours as controls placed them in a more favourable position for regression. Consequently there can be no doubt as to the effect of treatment. Moreover, in the untreated animals metastatic deposits were common, but in none of the animals which died while still under treatment were any metastatic deposits found.

There is a marked naked-eye difference between a treated and an untreated growth. The treated tumour is composed mainly of a necrotic core with only a narrow margin of tumour tissue proper. The width of this bounding layer depends upon the size of the tumour and the duration of the treatment. Of course, necrosis occurs also in the centre of many untreated tumours, but growth continues at the margin, so that there is always an increasing area of tumour tissue in growing tumours.

The facts mentioned above and in our previous communication, made it likely that there would be some difference in the hæmolytic content of the blood against cobra venom in susceptible and refractory animals respectively. We find that the anti-hæmolytic power of tumour-bearing rats is considerably less than that of refractory animals. Further, in uninoculated animals, it is possible by an examination of the anti-hæmolytic power of the blood to foretell with a considerable degree of accuracy whether on inoculation with sarcoma they will or will not "take." The method of our procedure will be given in detail in another paper, but we may mention here that inactivation of the serum to be tested is essential. Conversely, by diminishing the anti-hæmolytic power of otherwise refractory animals it is possible to render some of them temporarily susceptible—in one instance even after ten previous unsuccessful inoculations with the same tumour.

In the human subject the results are not so unequivocal. Infective conditions seem often to be accompanied by a considerable loss of anti-hæmolytic power to cobra venom, and all we can say is that serum from cases of sarcoma also assists hæmolysis, while that from normal individuals tends to inhibit it. This similarity with infective conditions may have a suggestive significance.

To summarise: 1. By an extension and modification of

[1] Part of a paper read before the Leeds and West Riding Medico-Chirurgical Society on Feb. 16th, 1912.

[2] THE LANCET, April 1st, 1911, p. 879.

previously described treatment it is possible to cure large inoculated sarcomata in rats in about 70 per cent. of cases. 2. The blood of "positive" animals with tumours does not prevent, but appears to assist, hæmolysis by cobra venom in vitro. 3. The blood of "negative" animals inhibits the hæmolytic action of cobra venom in vitro. 4. The blood of uninoculated rats, by the occurrence of inhibition or the reverse, indicates whether the animals will be refractory or susceptible to inoculation. 5. The blood of normal human individuals also possesses inhibitory properties, and these have been diminished in all the cases of sarcoma examined up to the present.

Note.—Since this paper was read one human inoperable recurring sarcoma has shown marked diminution in size and relief of symptoms under treatment.

Leeds.

THE TREATMENT OF TALIPES EQUINO-VARUS.[1]

BY EDRED M. CORNER, M.C. CANTAB., F.R.C.S. ENG.,
SURGEON AND LECTURER TO ST. THOMAS'S HOSPITAL AND TO THE CHILDREN'S HOSPITAL, GREAT ORMOND-STREET, ETC.

I INTEND considering with you to-day some methods of treating cases of deformity of the foot termed talipes. It is unfortunately a condition which is distressingly frequent, particularly calling for energetic treatment in hospital patients. Unfortunately, it is often associated with infantile paralysis, anterior poliomyelitis, so that it is impossible for us to reconstruct a perfect foot. All that can be done is to make the best of a "bad job."

In order to do this we must remember that the foot is of use in standing, walking, running, &c. This being its main function, the appearance of the "pretty, dainty, little foot" is very secondary and comparatively unimportant. Our aim and object should be in consequence to give the patient a serviceable foot upon which he can stand, walk, or run. Anything short of this is tantamount to imperfect success or failure.

There are, I think, two points in the treatment of talipes upon which all are agreed: the younger the age at which treatment is begun the better the chances of success, and that the treatment of talipes must not be short but must extend over a long period of months and years. Those who have most success in these cases are the surgeons who see and follow their patients for years; not those who do an operation and no more. This is in itself a very great difficulty, because every surgeon's hospital constitutes the great mine from which he extracts practice and experience; whilst at the same time it is very difficult, or almost impossible, to follow a hospital case for more than a short time. In consequence, our knowledge of the advantages and benefits derived from various modes of treating cases of talipes is largely deficient in evidence derived from cases years after treatment has been commenced. In consequence it is my intention to review before you such results as are obtainable.

Before doing so I would point out that it is right in a lecture delivered at a children's hospital to consider the treatment of growing subjects. In them the objective of all treatment is easily stated. It is to enable the foot to be used in the best way possible as a foot. For the treatment of deformities in growing subjects to be successful it must give a useful functional part, so that the constituents of the part grow under proper and normal functional conditions, such growth improving the part. But if treatment fails to give a good functional part, then the constituents of the part continue to grow under abnormal and improper conditions, their growth adapting itself to these abnormal conditions and making the deformity worse rather than improving it. The success of an operation lies in the ultimate usefulness of the part.

Massage, movement, and manipulation.—There is no doubt that this method forms the basis of all treatment for talipes. For its rationale and success it depends upon the concurrent growth of the constituents of the foot, the massage, movements, and manipulations making the ligaments, bones, and tendons adapt and fashion themselves properly as they grow, somewhat like a stick fixed in the ground enables a scarlet runner to grow properly. Thus by constant care, massage, and exercises the growth of the foot enables it to be moulded to the proper condition. If massage and exercises are neglected the growth of the foot continues under abnormal conditions and is, in consequence, improper, as is that of the scarlet runner which is not trained up a stick.

Amongst patients in the upper classes this treatment can be carried out thoroughly, but amongst hospital patients it will not be carried out. Losing in consequence the basis or backbone of treatment, it is obvious that hospital cases have to be treated differently from those patients in whom massage and exercise can be thoroughly done.

Massage, movement, and manipulation, aided possibly by such minor proceedings as tenotomies, form the basis of treatment for the first one to two years of life. If this treatment has been well carried out, and it is not a bad paralytic case, the child may then be able to get about properly on his feet. The subsequent growth of the feet, since he can use them properly, will also be proper, and complete the cure. But, as is so often the case amongst the poorer classes, massage, movement, and manipulation have not been successful in giving the child a foot on the sole of which he can walk. Then when the child has reached such an age as he can be taught to walk, it is the duty of the surgeon to give him a foot upon the sole of which he can walk. If this is done the subsequent growth of the foot will render the improvement permanent. But if the surgeon fails to give the child a foot on the sole of which he can walk, the case will not improve but go to the bad.

Cases must be most carefully watched even after apparently successful operations. How often do apparently successful cases come back after two to three years with the talipes imperfectly corrected. It can only be reiterated that the treatment of cases of talipes must be extended over years and not confined to the period of the operation. Success is attained by constant care, not by occasional treatment.

Tenotomies.—All tenotomies must be regarded as auxiliary proceedings which are not ends in themselves. The tendo Achillis is the tendon which is most often divided. Of late years it has been shown that the earlier movements and massage are begun in the treatment of fractures the quicker the recovery and the better the result. Recovery of power is often slow after tenotomies, so that it is often better to do the little operation of tendon-lengthening. The recovery is then quicker and more complete.

It must be clearly understood that all tenotomies and tendon-lengthenings are of no avail if not supplemented by other treatment. They are small and comparatively unimportant measures, merely accessory to the long treatment by massage and exercises.

Neurorrhaphies.—There is far too little known about nerve anastomoses in these cases for it to be possible than to do more than mention the method.

Tendon-graftings (tenorrhaphies).—This is one of the most useful and beneficial means of treating suitable cases of talipes. In the most successful class of cases the outer part of the tendo Achillis is attached to the peronei muscles. But two words of warning must be given: firstly, immediate and decided improvement must not be expected, even two years may elapse before success is attained; secondly, like tenotomies, tendon-graftings are merely adjuvants, so that treatment by massage and exercises must be persevered with throughout.

Osteotomies.—The only osteotomy at all often employed is one in which the tibia is divided horizontally just above the lower epiphysis. The fibula is then broken. The foot can then be rotated on the shaft of the tibia into the proper position it should occupy. Thus in talipes equinovarus with inverted adducted foot the toes can be turned out. Like tenotomies and tenorrhaphies this osteotomy is merely an adjuvant to the general treatment.

Ostiectomies.—This is not a pretty word, but it is merely meant to imply those operations in which bones are removed. Personally I regard them as most important means of treating talipes. For if the deformity has existed long enough for the bones to have become deformed, which is almost always so, as skiagraphs show us, there are then only two methods of reducing the deformity: either slowly, by the action of growth under treatment by massage and movements, or

[1] Based on a lecture delivered at the Children's Hospital, Great Ormond-street.

quickly, by means of an operation on the deformed bones. In hospital patients it is usual to prefer this latter method for reasons already stated.

Naturally our first inquiry is which tarsal bone is most affected, because towards such a bone we must first direct our attention. The answer to this question is decisive. The astragalus is deformed beyond all other bones of the foot. The most successful operations for talipes are directed to it. The neck of the bone has been divided, an osteotomy, with disappointing results. The head of the astragalus has been excised and the results ascertained to be unsatisfactory. The whole astragalus has been excised, and for a time this gave great satisfaction. But the ultimate results have been unsatisfactory, and the unsatisfactory foot perfectly typical. The foot was curved, the toes pointing inward, with a tendency for the calcaneum to turn under the tibia and lie on its outer side. From the functional point of view these were useful feet; but from the cosmetic point of view they failed.

The operation was extended and the anterior third of the calcaneum removed with the astragalus, and the foot put up in plaster in good position. The remote results of this proceeding were better than from an astragalectomy alone. But yet a further improvement was introduced. It was obvious that by preserving the ankle-joint a better functional foot could be secured. This was done by removing the head of the astragalus, the anterior part of the calcaneum, and the contiguous parts of the scaphoid and cuboid until the foot could be placed in good position. The results were disappointing, the probable explanation being that the mid-tarsal joints were destroyed. A return was therefore made to the removal of the astragalus and front part of the calcaneum, in which the ankle-joint and the mid-tarsal joints are thrown into one, rather than destroyed. In the present state of my experience and knowledge, I have found that this operation yields the best anatomical and physiological result in a foot the subject of the deformity of talipes equinovarus.

There remains a superlatively important item in the treatment to be mentioned. Massage, manipulation, and movements must be continued, in addition to standing, walking, running, skipping (with boot and irons if necessary); and the case watched for some years or until growth ceases and a satisfactory result is assured. Wrenchings under an anæsthetic, plaster-of-Paris splints, tenotomies may be required, and all idea that the big operation was final or that the need for these secondary operations reflects discredit on the original operator banished from the doctors' and relatives' minds. It is constant care and constant operations which bring about good results. Anything short of this is deservedly unsuccessful.

In conclusion, let me remind you that the period of life in which all deformities are most satisfactorily treated and corrected is that of childhood when rapid growth and active tissue changes are taking place.

Harley-street, W.

THE VALUE OF PNEUMOCOCCUS VACCINE IN THE TREATMENT OF PNEUMONIA.

BY NATHAN RAW, M.D. DURH., M.R.C.P. LOND., F.R.S. EDIN., D.P.H.,

PHYSICIAN, MILL ROAD INFIRMARY, LIVERPOOL.

I THINK all of us agree that there is something more to elucidate regarding the exact pathology and treatment of the pneumococcal infections. When we are called upon to attend a patient suffering from pneumonia we instinctively feel a sense of danger for the patient and a feeling of great uncertainty regarding the result. Even if all the symptoms are favourable and the patient feels comfortable we as doctors have anxious moments until the welcome crisis comes and the virulence of the attack has spent itself. The man who has the best chances of recovery from acute pneumonia is he who has a sound circulatory system, which of course includes sound heart, muscle, and reasonably elastic blood-vessels. I have, however, long been of the opinion that we are still as a profession at a disadvantage in the treatment of this virulent disease, and our ordinary methods are not sufficient for the attack. We require some weapon which will destroy the virulence of the pneumococcus and its products and produce a rapid immunity in the blood against it.

Naturally, we turn to some remedy which has been prepared from pure cultures of the pneumococcus of Fraenkel, and it must be either in the nature of a vaccine or a serum. It has been found extremely difficult to prepare a serum from the pneumococcus on account of the insusceptibility of animals to true pneumonia. A vaccine to be potent ought to be autogenous—that is, it ought to be prepared from sputum or blood of the patient himself; but this is a matter of great difficulty, as the disease being of such an acute and short duration has either subsided or terminated fatally before the vaccine can be got ready, and it might be borne in mind that to be of real value the vaccine must be injected early in the illness; in fact, if it can be used on the first or second day it acts at times almost miraculously. If we have to wait until the fourth or fifth or sixth day when there is a general pneumococcic blood-stream infection the vaccine is of little value, and seems to exert little or no influence on the course of the attack.

We are thus compelled to use a stock vaccine or a homologous vaccine prepared from a pure culture of pneumococci isolated from the blood of a patient suffering from lobar pneumonia. In this we are at a great disadvantage, because the strains of pneumococci vary considerably in their virulence and characteristics, so that we are not certain that we are using a vaccine prepared from the same infection as that with which we are dealing. In spite of this disadvantage, however, the results with a stock vaccine are most valuable, and in cases in which I have used vaccine for pneumococcal infections the encouragement has been so great that I will certainly persevere with it in every case.

The total number of cases of pneumonia in which we have used vaccine during the last two years has been 207, the great majority of them being treated in hospital. This number does not represent all the cases with which we have had to deal, as in some simple cases without any complication it was not found necessary to resort to vaccine treatment, whilst in a great many advanced cases which were obviously dying on admission to the hospital it was not considered desirable to administer it. I have, however, included in this list all the cases in which it was given, so that the results may fairly represent the value of the treatment. I must,

Table showing Results of Treatment in 207 Cases of Pneumonia.

Age.	Cured.	Died.	Total.
Between 1 and 10 years	28	2	30
,, 10 ,, 20 ,, ...	30	6	36
,, 20 ,, 30 ,, ...	31	4	35
,, 30 ,, 40 ,, ...	25	5	30
,, 40 ,, 50 ,, ...	42	8	50
,, 50 ,, 60 ,, ...	16	6	22
,, 60 ,, 70 ,, ...	1	3	4
	173	34	207

All the above cases were treated with vaccines (except two which had serum). Death-rate a little over 16 per cent.

however, say that after my experience with vaccine it has been found extremely difficult to estimate accurately the true value of the treatment, for the simple reason that we can never be certain that a case would not have recovered without its use, hence we can only be guided by our general impressions and observation of the clinical course after each injection. It is not necessary here to review the general treatment which was prescribed for each case; suffice it to say that each case was treated on orthodox lines, with the treatment of special symptoms as they arose, and where necessary alcohol was always freely given. In cases where pain was a symptom fomentations and poultices were applied and in no case was an icebag used. Temperature was always reduced with tepid sponging, whilst in cases of sleeplessness and mental irritability we found great relief with small doses of omnopon either given by the mouth or hypodermically.

Dosage.

The usual dosage recommended by some writers is from 10 to 50 million with half the amount for children. In my opinion these doses are too small, and to get the full effect of the vaccine it is necessary to give it in larger doses and at the earliest possible moment after the onset of pneumonia.

We usually commence with an initial dose of 50 million, followed in 24 hours, if necessary, by another injection of 100 million, and in some cases we have even given 150 million, with apparently excellent result. I consider the question of dosage by far the most important of all, and as the result of a large experience I am convinced that the vaccine itself is harmless, and I have never noticed anything but a good effect from its use. There can be no question that in a certain proportion of cases it appears to have no effect, and does not seem to influence the progress of the disease one way or another. On the other hand, in a great many cases an injection of a large dose is followed by a feeling of comfort and relief, associated with a rapid fall in the temperature and slight improvement of perspiration.

Effect on Crisis.

The administration of vaccine does not seem to have any appreciable effect in hastening the crisis in an ordinary case of pneumonia. The old teaching that pneumonia is a self-limited disease seems still to be true, and I cannot say that I have observed any shortening of the period of fever after the use of vaccine or serum. There is frequently a sudden drop of two or three degrees after a large injection of vaccine, constituting a sort of pseudo-crisis, but unfortunately after a few hours the temperature again rises until the true crisis appears. It seems to be necessary before a crisis occurs that a sufficient amount of anti-pneumotoxin should be formed in the blood to exactly counterbalance the amount of pneumotoxin.

The effect of vaccine on the pulse is always good, often reducing it in an hour by 30 or 40 beats, but in a few cases in which the blood pressure was taken no appreciable difference was observed.

Other Pneumococcal Infections.

Following the general rule of vaccines, we would expect to find better results in more or less subacute or chronic pneumococcal infections than in virulent pneumonia. I have only used vaccine in one such case—viz., a general pyæmic condition with numerous abscesses in many parts of the body, following an attack of lobar pneumonia. Undoubtedly we observed excellent results follow each injection and an apparently hopeless case was transformed into a complete cure.

The delirium which so frequently accompanies pneumonia of the apex is possibly explained by the direct lymphatic extension to the brain of a localised pneumococcal meningitis, and we have observed that in such cases the administration of vaccine is nearly always followed by diminution of delirium and a tendency to natural sleep, but often only of a temporary character. It would seem to me that the ideal treatment of pneumonia would be by means of an anti-pneumococcus serum, but so far we have not succeeded in obtaining one, owing to the difficulty in immunising an animal. I believe, however, that if the serum of a patient who has just had a crisis could be obtained in sufficient quantity it would act as a true antitoxin in a case of pneumonia, exactly as in the case of diphtheria.

In conclusion, I would like to mention that we have observed a notable absence of complications in those cases treated by vaccines. I do not wish to lay too much stress on this observation, but it is a fact that out of the whole 207 cases not a single empyema has resulted.

I am convinced that we have in pneumococcus vaccine a valuable aid in the treatment of pneumonia, and although not a specific remedy it ought always to be used in those cases of a virulent type which threaten the life of a patient.

I have to express my indebtedness to my colleagues, Dr. G. E. Williamson and Dr. G. W. N. Joseph, for their valuable help.

Liverpool

LITERARY INTELLIGENCE. — Messrs. Baillière, Tindall, and Cox announce for publication the following: "Acromegaly; a Personal Experience," by Leonard Mark, M.D., which will contain portraits and anthropometric data showing full course of the disease in a typical case; "The Treatment, Prevention, and Cure of Tuberculosis and Lupus with Allyl Sulphide," by W. C. Minchin, M.D.; and a new edition of Sir William Whitla's "Dictionary of Treatment."

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A FATAL CASE OF PROLONGED TOXIC COMA LASTING NINE DAYS.

BY I. C. MACLEAN, M.D. LOND.

THE patient, an unmarried woman, aged 41, who had been in the habit of taking veronal in from 7 to 10-grain cachets from a medical man's prescription for the last four years, inadvertently swallowed 90 grains one day at about 10 A.M. She was not seen by me till 3.30 P.M., when I found her in a state of profound coma; pulse 80; respiration 22 and stertorous; slight corneal reflex and knee-jerks were present. I washed out her stomach, which was found empty, and gave her 4 ounces of strong coffee with 2 ounces of brandy, also strychnine hypodermically. All reflexes had disappeared next day and she remained comatose, only recovering partial consciousness in the last 36 hours, when she made feeble attempts to swallow, recovered the use of her facial muscles, and moaned faintly in response to questions. She died with symptoms of acute broncho-pneumonia and acute hæmorrhagic nephritis on the ninth day. I bled her on two occasions, 1½ pints the first night, infusing 2 pints of saline solution intravenously, 1½ pints the second evening with 3 pints of saline solution intravenously, and I gave a third infusion of 2 pints of saline solution on the fifth day. Six-hourly feeds of 8 to 10 ounces were given with the œsophageal tube, the stomach being washed between each feed, which, consisting chiefly of a diluted mixture of milk, Valentine's meat juice, and brandy, was usually absorbed. Saline solution per rectum was occasionally given also. Great care was exercised with regard to oral cleanliness and I had the help of two excellent and attentive nurses; in spite of this, however, towards the end the upper air passages became very foul. Various stimulants were used at intervals—brandy, strychnine, pituitary extract, and digalen—while oxygen was administered freely. The temperature, which was subnormal for the first two days, gradually rose, being highest on the seventh day (105·6° F.). The average urine drawn off for the first six days was 24 ounces in the 24 hours; on the last three days only 9, 6, and 3 ounces respectively. There were no convulsions. Towards the end fatty, hæmorrhagic, and granular casts were abundant, but no hæmatoporphyrin was detected. The infusion of saline solution was always followed by marked improvement of the pulse, respiration, and general condition, and up to the fourth or fifth day I had serious hopes of saving the patient.

Knightsbridge, S.W.

NOTE OF A CASE IN WHICH ONSET OF DIABETIC COMA SIMULATED APPENDICITIS.

BY J. S. B. STOPFORD, M.B., CH.B. VICT.,
SENIOR HOUSE SURGEON, ROCHDALE INFIRMARY.

AFTER reading an annotation in THE LANCET of Feb. 10th (p. 378) on Abdominal Pain as a Premonitory Sign of Diabetic Coma I thought a few notes on the following case might be of interest.

A boy, 12 years of age, was admitted to the Rochdale Infirmary at about 11.30 A.M. on Dec. 8th, 1911, having been sent in as a case of acute appendicitis probably requiring immediate operation. He had been suddenly taken ill during the previous night with pain in the lower abdomen which was so severe that he was compelled to flex both thighs. He suffered from flatulence and vomited once a little thick brown material which gave no relief. He passed flatus freely, and about three hours after the onset the bowels were moved and the motion was normal. The pain became a little easier after this, but he continued to have short attacks of very acute pain, chiefly in the right iliac region. The mother stated that up to 18 days ago the boy had never had a day's illness in his life, but about this time he began to

suffer from nocturnal incontinence of urine and complained of passing a very large amount of water.

On admission the patient looked acutely ill and appeared very drowsy. His face was "pinched" and quite "abdominal" in character. The whole body seemed wasted and the skin was noticeably dry and thin, and could be easily raised from the subcutaneous tissues. He complained of thirst and a nasty taste in the mouth, the tongue being dry and slightly furred. The pulse-rate was 120 per minute, weak, and of low tension; the respirations were 28; and the temperature was 97·4° F. The abdomen moved freely with each respiration, and there was no distension. The whole abdomen was tender on palpation, and this was most marked in the right iliac region, but no swelling could be felt. There was no tenderness in the loin, and nothing was found on examining per rectum. Within an hour of the time of admission the patient became more drowsy and the respirations became quite "sighing" in character. The drowsiness, the respirations, and the history given by the mother suggested the possibility of diabetes, and on obtaining a specimen of the urine shortly afterwards the specific gravity was found to be 1030, and sugar and diacetic acid were present. The boy was immediately put on large doses of sodium bicarbonate, both by the mouth and rectum, but in spite of treatment he sank into typical diabetic coma next morning and died 20 hours later. During the last 24 hours he had passed 80 ounces of pale urine containing 1400 grains of sugar.

At the post-mortem examination the appendix was found to be quite normal, and there were no macroscopic changes in the abdomen except some fatty infiltration of the liver and kidneys. Unfortunately permission was not granted to examine the brain, and through a mistake no microscopic sections were cut of the pancreas, &c.

This case illustrates extremely well how abdominal pain may be a premonitory symptom of diabetic coma and how necessary it is to make a systematic examination of the urine in all cases.

I am indebted to Dr. H. Harris, honorary surgeon to the infirmary, for permission to communicate these notes.

Rochdale.

NOTE ON A CASE OF FRACTURE OF THE LARYNX.

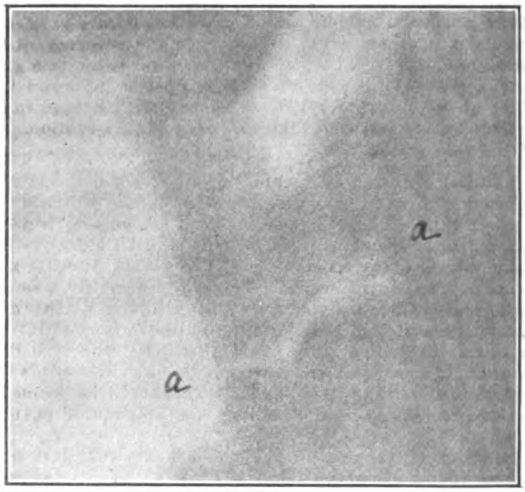
BY JAMES ANDREW, M.D. GLASG., D.P.H. CAMB.

FRACTURES of the larynx are fortunately extremely rare, and are usually the result of very severe violence caused by crushing or pressure directly over the cartilages. They are usually followed by very serious results, due, no doubt, to the extensive damage, not only to the cartilages, but also to the mucous membrane of the larynx. The following case is of interest, both on account of its exceptional causation and also because of its complete and rapid recovery.

On Oct. 9th, 1911, an engine driver, aged 43 years, called at my surgery complaining of pain in the throat and difficulty in swallowing. He gave the following history. On Oct. 6th he was following his usual occupation. While endeavouring to open the throttle of the engine he was seized by a violent attack of sneezing. He turned his head to one side, away from the fire-box, and immediately afterwards felt something "crack in his throat," and he could not sneeze owing to "cramp in the muscles of the throat." During the remainder of the day his throat was very painful, and he had difficulty in swallowing, but he was able to finish his day's work. On the 8th the pain was very severe, and he had great difficulty in swallowing. He complained also of salivation.

When seen by me on Oct. 9th there was no evidence of external injury. The neck appeared slightly swollen. The voice was husky, and swallowing was difficult and painful. Salivation was profuse. On lightly grasping the larynx between the finger and thumb and gently moving it from side to side, distinct crepitus was felt in the region of the thyroid cartilage, and I was of opinion that it was located in the right thyroid cartilage, though it was extremely difficult to define its origin exactly.

Dr. J. Walker Downie kindly examined the patient at the Western Infirmary, Glasgow, on Oct. 13th, and reported that there was crepitation on both sides of the pomum, chiefly at the lower border of the thyroid and upper border of the cricoid cartilages. He was of opinion that there was fracture of the cricoid cartilage. Two skiagrams were prepared, and from them it was seen that there was distinct fracture of the cricoid cartilage. There was also a line running obliquely across the thyroid cartilage near its lower border, which would seem to indicate fracture of that cartilage also (see figure).



Reproduction of skiagram of thyroid region. *a–a* indicates line of fracture.

The treatment consisted in wearing for 21 days a poroplastic splint moulded to the neck. During that time the pain in the throat completely disappeared, and the difficulty in swallowing and salivation gradually passed away.

The case is of interest chiefly on account of its causation. The muscles of the arms and chest were fixed in the man's endeavour to open the throttle of the engine, and in turning the head to one side he also fixed the muscles of the neck. The attack of sneezing brought the larynx into sudden contact with his collar, so that he fractured his larynx over the comparatively sharp edge of the collar.

I am indebted to Dr. Walker Downie and to Dr. W. F. Somerville, of the Western Infirmary, Glasgow, for report and skiagram of the case.

Coatbridge.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

LARYNGOLOGICAL SECTION.

Exhibition of Cases and Specimens.

A MEETING of this section was held on March 1st, Dr. STCLAIR THOMSON, the President, being in the chair.

The PRESIDENT exhibited: 1. A Larynx showing Epithelioma removed post mortem from a man aged 23. The case had been shown before the section a year ago, and attention was drawn to the early age at which the disease had appeared. 2. A case of Combined Tuberculosis and Syphilis of the Larynx in a woman. The patient had no physical signs in the chest, but the Wassermann test was positive, and tubercle bacilli had been found in her sputum. The larynx showed deposits of tubercle and syphilis each in typical form. 3. Double Abductor Paralysis in a man, aged 42, in whom a skiagram indicated a mediastinal tumour.

Dr. H. J. DAVIS showed a case of Double Abductor Paralysis in which he proposed to perform thyrotomy with the object of removing completely the left arytenoid and vocal cord. (A conflict of opinion arose in the discussion on the question of the advantages which such an operation would have over tracheotomy, the majority of the speakers expressing themselves as favouring the latter.) Dr. Davis also exhibited the following series of cases and specimens: 1. A Grain of Indian Corn which had been retained in the nose for
